The special committee appointed to deal with the water-supply have issued their report. It states that they decided to invite specifications and tenders from practical well-sinkers for securing a daily supply of 150,000 gallons of water. In February it was reported that 70,000 gallons were obtained from the well sunk, and in addition 40,000 gallons from the corporation. It was recommended that another borehole should be put on at the bottom of the present well, at a cost of £500 or £600. The committee did not advise this, preferring to give the present arrangement a fair trial, as the quantity was increasing. The corpora-

Digitized by Google

tion charged 6*d.* per 1000 gallons, the amount used being 130,000 gallons a day; so it was expected that a saving would be effected by the present plan of obtaining the supply.

Singular Deaths.

An inquest was lately held on the body of a man aged fifty-six, whose death was said to have been aggravated by taking large quantities of chlorodyne. He began by taking a few drops, and lately took a whole bottleful at once. He was found unconscious, and died soon afterwards. The heart was found to be fatty and atrophied. The second case was that of a child aged four years, who died from inflammation of the brain, caused by the presence of a bean in the ear. Attempts had been made to extricate this without success, once under chloroform. Some censure was administered to the father of the child for not keeping the deceased under medical care, after having been told to do so.

Birmingham, April 20th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Assizes.

THOUGH the number of prisoners was large, and the nature of the crimes with which they were charged was grave, this last assizes has passed without any death sentence. The most serious feature in the calendar was the large number of criminal assaults upon women and children, in some instances by several men acting in company. Very severe sentences were passed upon those who were convicted, and it is to be hoped that these will have an effect in deterring others from committing such crimes.

A Drunkard's Tercentenary.

A woman whose name betokened her Irish nationality was brought before the magistrate on the 16th inst. for the 299th time! She was fined 10*s.* and costs, or ten days' imprisonment. It is almost certain that the wretched woman will complete what has been ironically termed her tercentenary. It is to be lamented that there is not some more satisfactory method of dealing with this and similar cases.

The Weather and the Easter Holidays.

In Liverpool, as elsewhere, the weather which prevailed on Easter Monday was wintry in the extreme, in spite of which there were a large number of cheap trippers who braved the miseries of a ferry passage under such inclement auspices. Although there was a falling off in the total number from that of last year, it was still very large, and it is satisfactory to learn that there have been no casualties.

April 20th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Durham Colliery Doctors and the Strike.

A DURHAM "Colliery Doctor" writes a strong letter to one of our local papers, in which he shows very clearly the heavy loss which is sustained by the colliery surgeons, owing to the loss of the miners' fortnightly subscriptions, which are deducted at the office, when working, from their pay. It is computed, he says, that 70,000 men are on strike, whose subscriptions to the doctors amount to £1750 per fortnight. To this must be added losses from non-payment for confinements, vaccination, &c., and further non-payment by small tradesmen and others dependent on the men; so that the total loss to the doctors cannot fall short of £2500 per fortnight. The worst of it is, the doctor is expected and does attend all these people at present free, and has besides to keep up his usual expenses of assistants, drugs, servants, and horses just the same as if he was being paid. "A Colliery Doctor," as a remedy, suggests that the men may be asked to pay up the arrears by degrees when they get to work, which arrears, with their consent, might be stopped at the office as before. He believes that this is a fair proposition to make to the men, and he believes that they will accede to it. He further asks for a meeting of colliery doctors to be held in Durham next week to bring this important matter before the men. He also fears that there is much work before the colliery doctors in the coming season, owing to the insanitary condition of the colliery villages from overflowing of ashpits, the effects of inferior food, insufficient clothing, &c. As bearing this statement out, I see that the medical officer of health for Willington has reported an outbreak of scarlatina there, and reports that the ashpits in the colliery rows were overcrowded with refuse. At the Durham School Board meeting, too, a serious outbreak of measles is reported; one of the schools was closed till May 1st, about seventy of the scholars being ill.

North Riding Infirmary, Middlesbrough.

The annual report of the North Riding Infirmary at Middlesbrough has been presented to the meeting of governors, and it shows that 614 new patients had been admitted, making a total of 663 who had received treatment. The revenue fell short owing to the decrease in workmen's subscriptions, consequent on closing of works. Reference is made to the loss the infirmary sustained through the deaths of Drs. Ketchen and McCuaig. The late Duke of Devonshire had also proved himself a friend of the institution.

Death of the late Treasurer of the Cumberland Infirmary.

The death of Mr. William Parker, J.P., of Careton-hill, is announced. Mr. Parker, who was about seventy-five, died rather suddenly from cerebral hæmorrhage after two days' illness. He was until recently treasurer of the Cumberland Infirmary at Carlisle, and entirely through his efforts the jubilee fund of £2500 was collected for the institution. Mr. Parker was a great favourite in Cumberland; he was a thorough sportsman, and a good shot—in fact, a type of the fine old English county gentleman.

Newcastle City Lunatic Asylum Extension.

The competitive plans for the important extensions of the City Lunatic Asylum, which will practically make it a new building when carried out, have been exhibited for some days in our Town Hall, and have attracted many visitors. The plans of Mr. J. W. Dyson of Newcastle have received the first premium, and will be adopted for the buildings.

Seaside Summer Camp for Poor Boys.

The annual report of this most deserving association, which provides a seaside holiday for poor boys every summer, has been issued. It shows that 209 poor boys, hailing in about equal proportions from Newcastle and Gateshead, were afforded a pleasurable and health-giving holiday in the camp on Hartley Links, which was open during the last season for 133 days. There had been no serious sickness in the camp, and there were only six cases of flagrant disobedience and insubordination entailing dismissal.

Ambulance Work in the North.

At Jesmond the Mayor and Mayoress of Newcastle have presented certificates to the members of the ambulance class who have passed the examination in first aid, under the auspices of the St. John Ambulance Association. Dr. Aitchison, the instructor, at the same time received a presentation from the classes.—At Hartlepool, the Mayoress has presented the certificates and medallions to the successful members. Dr. Ainsley, the instructor, was highly complimented on his work.—At Gainford, Durham, Dr. Ellerton of Middlesbrough examined and passed fifty-two candidates for the St. John certificates of efficiency, and a vote of thanks was given to Dr. Hickey for his kindness in giving the lectures, and the painstaking way in which he had instructed the classes.

Sudden Death of a Middlesbrough Cyclist.

On Saturday morning a young man aged twenty-two died at a hotel at Great Ayton in Cleveland from syncope brought about by over-exertion and cold. He was taken ill the previous night after a ride of forty miles. Two local medical men were sent for, and remained with him all night until his death.

Mr. Page's case of pyloroplasty, or Mikulicz's operation, at the Royal Infirmary, which I noted in this letter on March 15th, has done well, and the man has gained two stones in weight.

Newcastle-on-Tyne, April 20th.

Digitized by Google

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Graduation Ceremony at Edinburgh.

ON Thursday of last week the spring graduation ceremony at Edinburgh University took place. Among those presented for the honorary degree of LL.D. was the Hon Sir Charles Tupper, of Nova Scotia, who is a Doctor of Medicine of Edinburgh of 1843. Several gentlemen received the degrees of M.B., C.M., and M.D., but most of those presented were graduates in Arts, Science, or Divinity. Professor Carystal, of the chair of Mathematics, delivered the address to the graduates, taking for his theme the changes in the Arts curriculum and the influence and aim of University education.

Inspection of Food in Edinburgh.

Two additional food inspectors for the city are to be appointed, and it is satisfactory to note that the Public Health Committee have decided that these new officials are to be qualified veterinary surgeons. The salary of each inspector is to begin at £125 per annum.

Victoria Infirmary, Glasgow.

This infirmary is certainly not falling behind in material prosperity. In addition to the various large sums which have recently been received by it, a sum of about £35,000 now reverts to it through the death of a lady, widow of the late Lieutenant-Colonel Sharp. The Victoria Infirmary is the youngest of such institutions in Glasgow, and though some of those most experienced in such matters had some misgivings as to the propriety of adding to the number of our medical charities, it seems clear from the support it has received, and the amount of work being done within its walls, that it justifies its claim to be recognised as one of the established and useful charities of the city. The new buildings in connexion with the infirmary are progressing satisfactorily. One of them, the Nurses' Home, in which the nursing staff will be lodged, is finished, and was opened to-day (April 19th) by Mr. and Mrs. Renny Watson, who had made a donation of the sum necessary to furnish the home in commemoration of their silver wedding. The other building, consisting of a new pavilion, which will double the accommodation within the infirmary, is also making progress, and should be ready for occupation early next year.

Health of the City of Aberdeen.

The following cases of zymotic diseases were notified to the medical officer of health last week: Measles, 1; scarlet fever, 6; diphtheria, 5; typhus fever, 3; whooping-cough, 39; erysipelas, 6—total 60, being a decrease of 24 as compared with the previous week. There were no cases of smallpox, typhoid fever, or puerperal fever. In his report for the month of March, Dr. Hay states that the total death-rate (23·71 per 1000 per annum) is somewhat higher than the preceding month, and is considerably higher than in March of last year. As regards the mortality at different periods of life, the death-rate among aged persons has been exceptionally high, amounting to an annual rate of nearly 11 per cent. The death-rates at the other age periods show no marked deviation from the normal. The mean age at death was higher than usual, being 39·7 years, as against 36·6 in the preceding month, and 35·3 in March of last year. Compared with the corresponding month in the previous ten years, the past month exhibits a total death-rate which is higher by 1·85 per 1000 than the average. Cases of typhus fever have shown a marked increase during the month, 16 as against 7 in February. Cases of typhoid fever numbered 20 (which is unusually large) during the past month, as against 11 in February. Diphtheria also showed an increase, 10 cases being reported, of which 8 terminated fatally. Erysipelas showed a distinct decline, and there were no cases of puerperal fever.

Resignation of Professor Ogston from the Staff of the Aberdeen Royal Infirmary.

The announcement on April 12th of the resignation of Professor Ogston came as a surprise to all. Universal regret is being expressed, and a hope that such a disaster to our medical school may be averted is entertained. A largely-attended meeting of medical men, representative of the city and county, was held on April 18th at the residence of Dr. Ogilvie Will, for the purpose of considering what steps should be taken to induce Professor Ogston to reconsider his determination to resign the office of surgeon to the Aberdeen Royal Infirmary. Dr. Ogilvie Will presided. The following resolution, proposed by the chairman, and seconded by Dr. Jackson, was unanimously carried:—"That this meeting regards Dr. Ogston's withdrawal from the staff of the Aberdeen Royal Infirmary as a serious and almost irreparable loss to the institution, to the University, and to the general community; and that it pledges itself to use every effort to induce Dr. Ogston to continue in the office which he has for so long conspicuously adorned."

Another resolution was proposed by Mr. Profeit, Balmoral, seconded by Dr. MacGregor, and unanimously agreed to:—"That a deputation from this meeting be appointed to wait on the directors of the Aberdeen Royal Infirmary for the purpose of urging on them the extreme advisability of their using every means in their power to retain Dr. Ogston's invaluable services for that institution." The deputation appointed consisted of Dr. Ogilvie Will, Dr. Jackson, Mr. Profeit, and Dr. MacGregor.

An enthusiastic mass meeting of students was held in Marischal College yesterday afternoon to consider what steps could be taken with regard to Dr. Ogston's resignation. A resolution was unanimously carried expressing deep regret at Dr. Ogston's resignation, recognition of his great eminence as a surgeon and invaluable service as a clinical teacher, and begging him to reconsider his decision. A deputation was appointed to lay this resolution before Dr. Ogston, and send a copy to the directors of the infirmary.

Summer Session at Marischal College.

The summer session commenced on April 18th. There was an average attendance of students. Those commencing their medical studies now enter under the new regulations, and, therefore, begin a curriculum of not less than five years.

April 19th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Abolition of the Office of Visiting Physicians to Irish Lunatic Asylums.

THIS rule, which has recently come into operation and has caused such an outcry, was suggested, it may be stated, in a report prepared by Sir Arthur Mitchell, Mr. Holmes, and Mr. F. F. MacCabe, three gentlemen thoroughly acquainted with lunacy administration and lunacy legislation. It has been alleged that by the new arrangement an inspection from outside the resident officials becomes impossible, and that there are no safeguards as regards the management of the insane, and no person holding a position independent of the administrative officials. Those who make these statements appear to forget what has already been pointed out—viz., that each lunatic asylum is visited by governors, inspectors of asylums, chaplains, and that information could, if necessary, in many instances, be obtained from patients discharged cured, or from their friends who had visited them. Besides this, the visiting physician is replaced by a resident, who can be responsible for the proper treatment of the insane during the absence of the medical superintendent on leave of absence, and that a consultant can be called in when so desired in any case requiring his services.

Adelaide Hospital, Dublin.

It is satisfactory to learn from the recent annual meeting that the hospital is at present in a very flourishing condition. Ten new beds have been added, and the institution has now 136 beds open for the reception of patients. It is contemplated to supply a long-felt want—namely, a convalescent home, where those who leave the hospital may for some short interval be cared for before their return to work. It is hoped that the home may be built before next winter. The hospital is an excellent one, thoroughly well managed, and the expenditure, some £6000 yearly, is well recouped by the immense good done to the suffering poor.

Systematic Lectures in Hospitals.

The medical board of St. Vincent's Hospital intend making an application to the Council of the College of Surgeons, requesting them to recognise the systematic courses of lectures in medicine and surgery which the medical staff propose to deliver. They consider that these

Digitized by Google

lectures delivered in hospitals could be largely extended without any additional cost to the student. The term that no "additional cost" will be incurred is somewhat ambiguous. It may mean that the authorities of the hospital in question intend charging, in addition to the ordinary hospital fees, the sum of 6 guineas for lectures in medicine and surgery, the same as charged by the medical schools, or, happily for the student's pocket, they may remit this item altogether. The board are of opinion that a hospital is *primâ facie* the proper place to teach medicine and surgery, and state that, acting on this view, the Senate of the Edinburgh University have recently recommended to the General Medical Council that lectures in these subjects should be transferred from the medical schools to the hospitals. It is, however, very improbable that the Council of the College will see their way to grant the request of the memorialists in the matter, more particularly as it would sensibly decrease the income derived by the schools of surgery which are under the control of the College.

Kilkenny Lunatic Asylum.

A large number of the governors having resigned office in consequence of the Board of Control having purchased additional land for the use of the asylum contrary to their wishes, his Excellency the Lord-Lieutenant has forwarded a communication to these gentlemen through the Under Secretary, which has caused them to reconsider their determination, and they have accordingly resumed office. He points out that the responsibility for seeing that lunatic asylums are properly equipped in the matter of land has been cast upon the Board of Control, but he acknowledges that the law in this respect is capable of improvement, and states that the Government hope when an opportunity arrives to legislate on this and other points connected with lunacy administration.

Superannuation of Poor-law Medical Officers: Deputation to the Chief Secretary.

On Tuesday, the 19th inst., a deputation waited upon Mr. Jackson at Dublin Castle for the purpose of urging upon him the desirability of promoting a Bill in Parliament, in order to give poor-law officers superannuation amounting to two-thirds of their salaries and emoluments after thirty years' service. The deputation included representatives from the following corporations and associations—viz., Royal College of Physicians, Royal College of Surgeons, Irish Graduates' Association, Irish Medical Association, British Medical Association, and Poor-law Officers' Association. The proceedings were private—a matter to be noted, seeing that Mr. Jackson was not able to receive the deputation at first, and that it is generally believed that he is averse to the proposed Superannuation Bill. Silence under these circumstances cannot be regarded as a favourable omen, and I fear the chances of obtaining Government support in the passing of the proposed measure are very slight indeed.

The Belfast District Lunatic Asylum.

From the sixty-second annual report of the Belfast Asylum I learn that during 1891 there were 203 admissions, which, with those already under treatment, make a total of 856. There were 31 deaths and 154 discharges, leaving a total of 671. Of the 203 admitted, 163 were cases of first attack, and 40 had been treated in the Belfast or other asylums before. As there has been no decrease in the number of admissions as compared with former years, the asylum accommodation has been greatly strained to meet the exigencies of the treatment of those admitted. In their memorandum of inspection on October 12th, the two inspectors of lunatics (Dr. G. P. O'Farrell and Dr. E. M. Courtenay) say that no post-mortem examination has been held during the year; but they trust that with the proposed alterations and improvements a suitable pathological room will be fitted up, as in so great a centre of medical science as Belfast the asylum should not be behindhand in the means of scientific research connected with the study and pathology of diseases of the brain and nervous system. It has now been arranged, they say, to meet the overcrowded condition of the asylum, to build a new asylum in the county of Antrim, and the existing institution

suggestion of the inspectors of lunatics, have decided to erect a detached hospital to accommodate fifty patients.

Ballymena Union Hospital.

For the post of medical officer of the Ballymena Workhouse, vacant through Dr. Kidd's death, there was a very keen contest, and on the day of the election (April 13th) Mr. Davidson was appointed by one vote, 24 voting for him and 23 for his opponent.

Extraordinary Mode of Testing Rabies.

A few days ago a calf was bitten in Market-hill, Portadown. That it suffered from rabies was established in a primitive fashion as follows. A black hen was placed in front of the calf, and according to the local veterinary surgeon it was expected that if the calf were mad it would become excited and plunge at the hen. In this instance the calf did not in that fashion, and those who witnessed the test were satisfied of the existence of the disease. The veterinary inspector having examined the calf afterwards, and having by a different method diagnosed the presence of rabies, the animal was destroyed.

The Guinness Trust Committee have expended £6000 in the erection of tenements close to Thomas-street, Dublin. The first block has been open since New Year's Day, and the second was opened early last month.

Mr. F. Alcock Nixon, surgeon to Mercer's Hospital and Professor of Surgical Anatomy Schools of Surgery, is a candidate for a seat on the Council of the College of Surgeons at the annual elections in June next.

Mr. Donovan has been appointed medical officer of Edgeworthstown Dispensary.

Belfast, April 20th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Protective Power of the Bacillus of Avine Tuberculosis against the Human Micro-organism.

SOME months ago, when Koch's tuberculin was the principal topic of conversation, the medical press seemed to be absorbed in the study of new remedies levelled at the giant tuberculosis. The comparative silence on the subject which has reigned for some time might have led some people to believe that the disappointment experienced at that epoch had paralysed all fresh efforts in this direction. A communication just made to the Académie des Sciences by MM. Héricourt and Richet (the last-named *savant* is still spoken of as M. Charles Richet, to distinguish him from his celebrated father, now dead and gone) disproves this conclusion. A reference to some of my previous letters will remind your readers that these twin observers had—unsuccessfully, alas!—attempted to render monkeys refractory to the invasion of human tuberculosis by the previous inoculation of the bacillus derived from the bird. Seeing this, the two *savants* turned their attention to the dog, an animal which is almost refractory to bird-tuberculosis, but very susceptible to the human variety of the disease. Four dogs were inoculated with cultures of human tubercle. Of these animals, two had previously received an intra-venous injection of bird-tubercle. The result was that the two unprotected dogs died in twenty-two days, whilst the two other animals are now, 122 days after the experiment, alive and well. It is thus fair to assume that the presence of the avine variety of the bacillus is inimical to the growth and development of the human species of that micro-organism.

Transmission by Inoculation of Chorea from One Dog to Another.

At the last meeting of the Société de Biologie, M. Babet reported that M. Triboulet, one of his pupils, had succeeded in transmitting from a choreic dog the disease to a healthy animal. The proceeding adopted was the following:—Having collected some blood impregnated by a choreic dog, this was cultivated, and the fertile culture was inoculated into three other animals. [illegible] already under the influence [illegible] by chloral [illegible]

trophic troubles. The third, aged three years, inoculated six months ago, is still alive, and presents all the symptoms of saltatory chorea identical with those found in the animal to whom he owes the disease. In this third dog there have also developed trophic changes of the nails and the skin, and a general muscular atrophy. His general condition is extremely grave. In the course of the discussion M. Nocard emphasised the importance of the fact that the dog rendered artificially choreic was an adult, seeing that in the puppy trophic and atrophic troubles with choreic movements were not unfrequently observed in distemper. These results seem to contradict the mechanical embolic theory of Kirkes and Hughlings Jackson; but it is not improbable that they will both be in time explicable on the microbian theory.

The Blood corpuscles as a Source of Animal Heat.

We are taught in text-books of physiology that the muscular system, the glands and the brain, are, in their relative order of importance, the chief sources of animal heat. Too little account has perhaps been taken of the thermogenic *rôle* played by the blood corpuscles. M. Mosso of Turin has recently communicated to the Société de Biologie the results of some experiments which appear to him to prove that the coloured elements of the blood are not entirely inactive in the maintenance of the standard of bodily heat. This observer, having previously curarised a dog, practised artificial respiration with hydrogen gas, so as to deprive the blood of any trace of carbonic acid. Sensitive thermometers were then inserted, on the one hand into the carotid artery, and on the other into different viscera of the animal; and it was noticed that directly artificial respiration with ordinary atmospheric air was commenced the mercury of the instrument placed in the carotid suddenly rose, while the column in the other instrument remained stationary. I must leave it to the experts to appreciate at their proper value these experiments, which we owe to a veteran who has worked for many years at the problem of the vascular mechanism.

French Surgical Congress.

The sixth session of this Congress was inaugurated last Monday morning in the great amphitheatre of the Faculty of Medicine. The room was decorated with the flags of different nations, and the blending of the colours of France, Russia, England, and other countries, once more proved that medical science is oblivious of artificial distinctions that unfortunately play such a large part in affairs mundane. The opening meeting was presided over by Professor Demons of the Bordeaux Faculty, the other gentlemen on the platform being Professor Lannelongue (Vice-President), M. Pozzi, the indefatigable secretary, and M Picqué, his lieutenant. Several papers were read by MM. Boiffin of Nantes, Masse of Bordeaux, Charvot of Paris, Routier of Paris, Auffret of Brest, Gross of Nancy, Villar of Bordeaux, Moty of Paris, Mony and Calot, on various subjects of surgical interest. A very full programme has been drawn up for the whole of this week, and visits have been arranged for to the great hospitals of the metropolis, where operations by such authorities as Verneuil, Terrier, Reclus, Bouilly, Nicaise, Guyon, Péan, Lannelongue, Lucas-Championnière, and others, will be performed. To-morrow, at 4 P.M., a visit will be made to the Institut Pasteur, and on Sunday operations will be witnessed at the Veterinary School of Alfort.

The Medical Profession in Japan.

From statistics recently communicated to the Comité d'Hygiène Publique by Professor Proust, we learn that that go-ahead country Japan boasts 38,620 practitioners of medicine. This, with a population of 40,000,000, gives one professor of the healing art to 1035 inhabitants. Unfortunately, 29,105 of these gentlemen are not provided with a diploma, and of the others, many possess qualifications which would hardly command confidence in European countries.

Hydrophobia and Muzzling.

Acting in conformity with a resolution passed by the Sanitary Council of the Department of the Seine, the Prefect of Police "invites" all owners of dogs who indulge in a walk in the public streets with their pets to either lead them by a string or to muzzle them. All stray dogs are to be secured and conducted to the pound, like our dear old friend Mr. Pickwick, of convivial renown.

Paris, April 20th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Measles Bacillus.

DRS. CANON AND PIELICKE of the Moabit Hospital here have discovered in the blood of measles patients a bacillus which they regard as the germ of that disease. They made this bacillus visible by staining preparations of blood with a solution of eosine-methylene blue. No other solution proved efficacious. When treated with the said solution the bacillus appears blue. Sometimes all parts are equally stained, sometimes only the edges of the middle part, and often the middle part is paler than the ends. The diameter of the bacillus is about equal to that of a red blood-corpuscle—but often much smaller. The component parts are frequently oblong, so that the bacillus looks double, or as if severed in the middle. It is often slightly curved, especially in the blood of patients in whom the disease has run its course. The bacilli were generally arranged in groups of from eight to twenty. They were found to be present during the whole course of the disease, but were most numerous during defervescence. They were detected in the sputum also, and in the secretions of the pituitary mucous membrane and the conjunctiva. Drs. Canon and Pielicke inoculated drops of blood taken from measles patients on the usual nutritive media, and found that the bacilli in question developed only in bouillon. They declare that the bacilli differ essentially from the micro-organisms of measles hitherto described.

Scientific Congresses.

The German Public Health Society will hold its annual meeting from Sept. 8th to 11th at Würzburg, just before that of the naturalists and medical men, which will begin on Sept. 12th at Nuremberg. The management of business connected with the former of these two congresses is entrusted to Dr. Alexander Spiess of Frankfort-on-the-Main.

Tuberculin and Mallein as a Means of Diagnosis.

At the instance of the Government of Baden, numerous experiments have been made at Karlsruhe on cattle with a view of testing the diagnostic value of tuberculin. All the animals which reacted were slaughtered and found to be tuberculous, while those which did not react were also slaughtered and found to be free from tuberculosis. It appeared that a dose of at least four decigrammes was necessary in order to produce a reaction in diseased animals. Two Russian veterinary surgeons, Kalning of Riga (who fell a victim to his experiments), and Hallmann of Dorpat, have applied the principle on which tuberculin is produced, and obtained from cultivations of glanders bacilli a substance, called mallein, which produces a characteristic reaction in horses suffering from that disease but not in others.

Appointments &c.

Professor Rumpf of Marburg has been appointed to succeed Dr. Kast, now professor of clinical medicine at Breslau, as head of the Hamburg Infirmary. His scientific publications treat mostly of diseases of the nerves.

Professor von Hippel of Koenigsburg is reported to have accepted a call to succeed Graefe as Professor of Ophthalmology at Halle.

Dr. Theodor Schuchardt, the founder of a chemical factory of world-wide fame, died at Görlitz on the 15th inst.

At a recent meeting of the City Deputies Professor Virchow emphatically condemned the mixing of religious propagandism with sick nursing.

Berlin, April 18th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

An Exposition of Modern Methods of Nursing.

THERE is much interest in the movement to display an emergency ward at the Columbian Fair, illustrating all the novelties connected with the system of modern nursing. An organisation has been effected for that purpose among the women physicians and trained nurses of Chicago. The spirit of emulation is aroused by the statement that a leading feature of the exhibit to be made by the women of Great Britain would be a complete exposition of the methods

Digitized by Google

of nursing employed in England, and which have attracted so much attention. It is suggested that the friendly rivalry thus created between foreign methods employed here would lead to important improvements in the service.

Failure to Pass the Army Medical Examining Board.

At a recent meeting of the examining board of the Medical Department of the army only two applicants passed successfully in a list of twenty-four. This examination is very severe and exacting, but the percentage of failures is very large.

The Pan-American Medical Congress.

The progress made by the projectors of this new organisation is very encouraging. Twenty-six nationalities are to unite in the incorporation which has been effected, and the officers have been elected and the regulations governing the body adopted. The president is Dr. William Pepper of Philadelphia. It is provided in the regulations, among other things, that the membership hereafter shall consist of such members of the medical profession of the western hemisphere, including the West Indies and Hawaii, as shall comply with the special regulations regarding registration—viz., the payment of 10 dols. for members residing in the United States, but no fee by foreign members. There is to be an executive committee, consisting of one member for each constituent country. There are to be twenty-one sections, covering every branch of medicine, surgery and obstetrics, and all the specialties. The languages of the Congress are to be Spanish, French, Portuguese, and English. The officers of each section are an honorary chairman, an executive chairman, who shall organise the work of the section and deliver an inaugural address, one English and one Spanish-speaking secretary, and one secretary resident in each additional constituent country of the Congress. The first meeting of the Congress is to be held in the City of Washington on Sept. 5th, 1893. The organisation is now complete in British North America, the British West Indies, the Spanish West Indies, Guatemala, Nicaragua, United States of Colombia, Brazil, Uruguay, Venezuela, and the Argentine.

The Death of Dr. D. Hayes Agnew.

Dr. Agnew had attained the age of seventy-four, but he was still very actively engaged in professional work. His reputation and his age placed him at the head of the profession in this country. His most important work was his treatise on surgery in three large volumes, which illustrated his immense capacity for work, and the range of his knowledge of surgery. By the public his name will always be identified with the case of President Garfield, the treatment of whose gunshot wound he largely conducted. He left a legacy of 50,000 dollars to the hospital of the University of Pennsylvania, and 1000 dollars to the College of Physicians of Philadelphia.

Consular Officers in Russia required to report the Existence of Typhus Fever in their Districts.

The danger of the importation of typhus fever from Russia is so serious that the State Department has issued a circular to American consular officers in that country requiring immediate reports on the prevalence of typhus fever in their consular districts. When there is urgency the report must be by cable. By this means our Government will be constantly advised of the sanitary condition of the emigrant ports of Russia and of the condition of the emigrants who embark for this country. The frequent occurrence of cases of small-pox on steamships from Liverpool is explained by the consul at that port to be due to the constant existence of this disease in that city. On March 5th there were twenty-nine cases under treatment in hospital. The consul also states that in several instances recently he has at the request of steamship companies appointed a physician to examine parties of Russian Jews migrating to the United States, and to have their baggage thoroughly fumigated.

Tuberculin a Test of Tuberculosis of Cattle.

In a herd of choice Jersey cattle kept near Philadelphia one cow died, and on examination she was found to have had tuberculosis. A veterinary surgeon examined the herd, but could detect no evidences of the disease in the other cattle. He, as an aid in diagnosis, he employed tuber-

care, many of the animals being imported. Every precaution had been taken to preserve the health of the stock and to increase their constitutional vigour. In-breeding has never been practised, and the greatest care had been taken to secure good ventilation, the choicest food, plenty of exercise, and pure water. Experts regularly examined the herd and everything pertaining to their health. In this instance the value of tuberculin in diagnosis seems to have been fully demonstrated. This experience has excited great interest among health officers, as it proves that there is a simple method of determining the condition of the herds which supply milk to cities. A question of importance has been raised in this connexion—viz., as to the danger of using the milk of healthy cows that have been inoculated with tuberculin. The best authorities do not regard the milk in such cases as in the least affected.

New York, April 11th.

Obituary.

DR. D. HAYES AGNEW.

By the death of Dr. Hayes Agnew, Philadelphia has lost its foremost surgeon, and a man whose sterling character commanded the respect of all who knew him. He was born in 1818, his father being a well-known physician. After a careful preparatory education he took his medical curriculum at the University of Pennsylvania, and first of all practised in the country. But he soon moved to Philadelphia, and quickly became famous as a teacher of anatomy, attracting large classes to his lectures and demonstrations. With his zeal in anatomy he combined a great interest in pathology and morbid anatomy, and he founded the Pathological Museum of the Philadelphia Hospital. At about this time also he started the Philadelphia School of Operative Surgery. This work brought him very prominently before the profession, and his promotion and success were now rapidly attained. In 1854 he was appointed surgeon to the Philadelphia Hospital, in 1863 he was elected surgeon to the Wills Ophthalmic Hospital, and Demonstrator of Anatomy and Assistant Lecturer on Clinical Surgery at the University of Pennsylvania. In 1865 he was appointed surgeon to the Pennsylvania Hospital and to the Orthopædic Hospital; five years later he was chosen Professor of Operative Surgery in the University of Pennsylvania, and in 1871 Professor of Surgery and Clinical Surgery in that institution and in the University Hospital. He retired from these public posts a few years ago, and latterly had largely withdrawn even from private practice.

Dr. Agnew's transparent honesty of character and unhesitating devotion to his profession won for him the admiration of all who knew him, and the students who attended his classes were his enthusiastic admirers. Dr. Agnew had a very accurate knowledge of human anatomy, which he took pains to keep up, and he combined with this a sound and wide knowledge of morbid anatomy. He was ambidexterous in a marked degree, and by long practice, as well as by natural gift, became a very skilful operator. Naturally, a man of such parts was greatly sought after, and it was generally felt when he was summoned to attend the late President Garfield in his dying illness that a proper selection had been made. He enjoyed the confidence of the profession and of the public in an equal degree. He was a great worker, and has left behind him a monument of industry and learning in the form of a System of Surgery in three very large volumes. A second edition of this work was rather quickly called for, and Dr. Agnew had the satisfaction of knowing that the results of many years of patient toil were highly appreciated by the profession. He has died at the ripe age of seventy-four, full of years and full of honour.

THE QUINTON MEMORIAL FUND. A meeting of the committee of this fund was held on [illegible] 14th ult. The finances showed a [illegible] Rs. 10,432 8 7 [illegible] Philadelphia Public [illegible] Medical [illegible] to the disposal of the [illegible] Quinton [illegible] the sum of [illegible] specific condition) to devote the [illegible] of a new ward for the Dufferin Hospital in [illegible]

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in subjects indicated at a recent meeting of the Examiners :—

Anatomy and Physiology.—Ernest Coleman, of Guy's Hospital; Wm. Hardcastle and Ernest H. Fricke, of Charing-cross Hospital; Francis J. Coutts, Alfred H. Gerrard, Thomas A. Starkey, and Joseph N. Brown, of University College; Nevill E. Thomas, of Middlesex Hospital; George G. Genge and Astley C. Swinhoe, of St. Thomas's Hospital; Thomas B. Bokenham and John S. Chater, of St. Bartholomew's Hospital; Harold S. Basden, of London Hospital; Oswin Shields, of St. Mary's Hospital; Victor J. Blake, of University College; David W. Wiseman, Charles W. Young, Walter E. Wyborn, and Edwin C. Montgomery, of Charing-cross Hospital; Garnet Soilleux, of Melbourne University; John Currie, G. A. Crace-Calvert, and Montague D. Eder, of St. Bartholomew's Hospital; Bertie J. Mayne, of Middlesex Hospital; Edward O. Thurston, of St. Thomas's Hospital; Graham N. Smith, Henry E. A. Horsford, and Paul C. E. Tribe, of King's College; Reginald L. Norman, of St. George's Hospital; E. H. Read, John A. Stainsby, and William Wilson, of London Hospital.

Anatomy only.—Lionel H. Y. Stephen and Edward Fisk, of Guy's Hospital; Algernon C. Bean, of University College; W. F. Adams, William P. Thomas, and John J. Spears, of London Hospital; Martin A. Cooke and Arthur H. Beadles, of St. Bartholomew's Hospital; Charles J. Barnes, of King's College and Mr. Cooke's School of Anatomy and Physiology; J. W. Stokes, of University College; John H. Wigham, of Yorkshire College, Leeds, and St. Mary's Hospital; Morris Wilks, of University College; William Gilbertson and Michael A. Teale, of St. Thomas's Hospital.

Physiology only.—Willie N. Barron, of St. Bartholomew's Hospital; Francis A. Phillips, of St. George's Hospital; Sylvestre A. Francisco, of King's College; Arthur R. S. Freeland and Geo. A. T. Hayden, of London Hospital; William C. F. Hayward, of Charing-cross Hospital; Arthur A. Lewins, of McGill College, Montreal, and Mr. Cooke's School of Anatomy and Physiology.

Sixteen candidates were referred in both subjects; four in Anatomy only and seventeen in Physiology only.

UNIVERSITY OF EDINBURGH.—At the graduation ceremonial held on April 14th at the University the following degrees were conferred :—

Doctor of Medicine.—John Ardern Ashcroft, England, M.B., C.M., 1885; Charles Henry Bedford, England, M.B., C.M., 1887, B.Sc.

Doctor of Science.—Charles Henry Bedford, M.D., B.Sc.

Bachelor of Medicine and Master in Surgery.—Charles Frier, Frederick William Mackay, Frederick Linney Pochin, and George Richard Wilson, England; Alexander John Mackintosh, Scotland; Alex. Orford Schorn, India.

Bachelor of Science.—Charles Templeman, M.D.

UNIVERSITY OF ST. ANDREWS.—The following gentlemen, having passed the required examinations, had the degree of Doctor of Medicine conferred upon them on April 14th :—

Ashworth, J. H., M.R.C.P. Edin., F.F.P.S. Glasg., L.S.A., Halstead.
Barber, Oliver, M.R.C.S., L.S.A. Lond., Sheffield.
Fleetwood, Wm. John, L.R.C.P., L.R.C.S. Irel., Aintree, Liverpool.
Hardwicke, William Wright, M.R.C.P., L.R.C.S. Edin., Dovercourt.
Hyde, Samuel, M.R.C.S., Buxton.
Jennings, Robert, M.R.C.S., L.R.C.P. Lond., Haslingden.
Langston, Thomas, M.R.C.S., L.R.C.P. Edin., L.S.A., London.
Lee, Edward Samuel, M.R.C.S., L.S.A., London.
Rigden, Walter, M.R.C.S., L.S.A., London.
Smailes, Thomas, M.R.C.S., L.R.C.P. Edin., Honley, Huddersfield.

At a Convocation held in Bishop Cosin's Hall, Durham, on March 15th, the following gentleman was admitted to the degree of M.D :—

Arthur Taylor Wear, M.R.C.S., L.R.C.P. Lond.

BARON HIRSCH (says *Truth*) has set an excellent example to wealthy sportsmen of all creeds and nationalities. He has decided to devote the whole of his turf winnings of last season, amounting in all to £7000, to hospitals and institutions of a kindred nature. The North-West London Hospital, Kentish Town, is to receive £1000, and University College, the London, and the West London Hospitals, and the Hospital for Sick Children, Great Ormond-street, will receive £700 each. Other institutions will benefit according to their needs and claims to support, without regard to religious or other distinctions.

FOOTBALL CASUALTIES.—In a match last week between the Keighley Shamrocks and Otley Shamrocks, at Highfield-lane, a player of the former team sustained a fracture of his left wrist. Whilst playing in a combination match on Wrexham racecourse, on Good Friday, a Gorton Villa forward was injured and removed to the Wrexham Infirmary, when it was found that he was suffering from concussion of the brain. During a game on Saturday at Handsworth, a young man, aged nineteen, received a blow in the abdomen and sustained "internal injuries." He was admitted to the General Hospital.

CENTENARIANS.—Thomas Jex, a master bricklayer, died at Wisbeach last week at the age of 104 years.—Mrs. Paulina Harris, who was born at Warsaw in 1790, died in Liverpool on the 10th inst. at the age of 102 years.

ROYAL INSTITUTION.—The Friday evening meetings will be resumed on April 29th, when Dr. Benjamin W. Richardson, F.R.S., will deliver a discourse on the Physiology of Dreams.

THE INFLUENZA EPIDEMIC.—Dr. W. J. Lush and Dr. J. P. Williams-Freeman, medical officers of the Andover Union, have each been voted a sum of £20 by the guardians, in addition to their salaries, as extra remuneration for the increase in their work resulting from the late epidemic of influenza.

NOTTINGHAM GENERAL HOSPITAL.—The annual report just issued for the past year shows that the daily average of patients in the wards was 144·4, which had exceeded that of any previous year since the hospital was founded; while it is satisfactory to notice that there was no proportionate increase in the domestic expenditure. Anæsthetics were administered in 515 cases. Through the convalescent fund thirty patients had been sent to convalescent homes. The adoption of a resolution two years ago that a delegate of the Hospital Saturday Committee should be selected to serve upon the board of management had been attended with very satisfactory results. The legacy of £500 bequeathed by the late Dr. Massey had been invested at his express desire. The hospital is indebted to the bankers in the sum of £979 2*s*.

THE ÆSCULAPIUS LODGE, No. 2410.—The last meeting of this Lodge for the present Masonic year took place at the Café Royal, Regent-street, on Wednesday, the 13th inst. The Lodge having been opened, Bros. Montague Cheale, Frank Reid, Edward Stock Bell, and Clifford Luxmore Drew, M.B., barrister-at-law, were admitted to the third degree by the W.M. Bro. J. Brindley James. Bro. C. Montague Simpson, M.R.C.S., having been duly balloted for, was elected a joining member. Bro. Deputy Inspector-General Belgrave Ninnis, M.D., R.N., was unanimously elected W.M. elect for the ensuing year. Bro. G. Danford Thomas was also unanimously elected treasurer. The Lodge, having enjoyed a most successful year, was closed until October. The brethren afterwards partook of a banquet, spending an enjoyable social evening which produced some capital vocal talent.

DIPHTHERIA IN BROUGHTY FERRY.—The Sanitary Committee of the Broughty Ferry Police Commission have resolved to cause a general inspection of the drainage of the burgh to be made, and have instructed the sanitary inspector, along with the medical officer and surveyor, to do so. In the course of their examination the officials have been instructed to devote particular attention to the drainage of the schools. After the inspection a report on the subject will be prepared and laid before the Board. The idea of providing a cottage hospital has also been mooted, and will probably form a matter for consideration—a site in the neighbourhood of Barnhill being mentioned as suitable. Several additional cases of diphtheria are reported; one of a rather serious nature has occurred in Brook-street. There have been occasional outbreaks of the disease in the burgh for the past twelve months, the first having been reported in March last year.

NATIONAL HEALTH SOCIETY.—The general meeting of this Society took place on the 11th inst. in the Committee-room, 53, Berners-street. The secretary's report, which was read and formally adopted, showed the important national character of the Society's work, and how greatly it had increased during the past year. Amongst the most important of the Society's work was that undertaken under the auspices of the County Councils in sending into the various counties of England competent teachers to deliver series of practical "homely talks" to the working classes on nursing, cookery, and health, seven different counties having applied for such teaching. The courses in almost every case comprise a tour of twelve weeks consecutively, with an average of ten lectures per week. The county lecturers have been trained principally by the Society. Amongst the lectures organised for the students' instruction a course on Sanitation was kindly given by Dr. Thorne Thorne, medical officer of the Local Government Board.

GIFT TO DORSET COUNTY HOSPITAL.—Colonel Williams of Bridehead, near Dorchester, has presented £1000 to this institution in memory of his father, the late Mr. Robert Williams.

PRESENTATION.—Mr. Chas. Sims, L.D.S. R.C.S., on his retirement from the chair of Dental Surgery at Queen's College, Birmingham, has been presented with a gold watch by present and past students and his colleagues.

HER MAJESTY'S GOVERNMENT having increased to £60,000 the grant of £25,000 originally made for the purposes of the British Section at the Chicago Exhibition, the Royal Commission for that Exhibition is enabled to dispense with the revenue it was proposed to raise by charging the exhibitors in proportion to the extent of space occupied, and therefore all space in the British Section will now be granted free of charge.

METROPOLITAN OPEN SPACES.—At a recent meeting of the Metropolitan Public Gardens Association it was announced that a legacy of £100 had been left to the Association (the first legacy it had obtained during the nine years of its existence). With regard to the Hilly Fields scheme, S.E., negotiations were pending to add four acres of glebe land to the forty-one acres it was proposed to acquire. About £6000 were still required to make up the purchase money. Steps were to be taken to secure several other grounds for the public use. The Duke of Westminster has presented the Edgar Field, at Handbridge, Chester, for the recreation of the poor children of that suburb, together with £1000 for its endowment. The grounds were formally opened by the Mayor of the city on Monday last.

BOOKS ETC. RECEIVED.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BAIN, JAMES G., M.B., C.M., has been appointed House Surgeon to the Taunton and Somerset Hospital, vice B. W. Housman, resigned.
BARRS, A. G., M.D. Edin., M.R.C.P. Lond., has been appointed Physician to the General Infirmary at Leeds.
BROWN, O. P., M.R.C.S., has been reappointed Medical Officer of Health for the Knighton Sanitary District of the Knighton Union.
CANT, WM. JOHN, M.R.C.S., L.R.C.P., L.S.A., has been appointed Honorary Consulting Surgeon to the Lincoln General Dispensary.
COTTERELL, EDWARD, L.R.C.P. Lond., M.R.C.S., has been appointed Surgeon to the Out-patients, London Lock Hospital.
CLEMONS, GEORGE E., M.B., C.M. Edin., has been appointed House-Surgeon to the Infirmary for Children, Liverpool.
DAVIES, SIDNEY, M.D. Oxon, M.R.C.S., has been reappointed Medical Officer of Health for Plumstead, Kent.
DRANE, E., L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Blakeney Sanitary District of the Towcester Union.
DONOVAN, P. H., M.B., B.Ch. Irel., has been appointed Medical Officer for the Dispensary District of Edgeworthstown and [illegible], Longford.
GIBSON, C. G., M.B., C.M. Edin., has been appointed Medical Officer of Health for the Rural Sanitary District of [illegible], vice Lunn, resigned.
GIBSON, JAMES, M.B., C.M., L.F.P.S. Glasg., has been appointed Medical Officer of Health for the [illegible] Cornwall Hospital, Penzance.

HARPER, H. C., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Stow Rural Sanitary District of the Stow Union, vice Smith.

HERSCHELL, GEORGE, M.D. Lond., M.R.C.S., has been appointed Physician to the National Hospital for Diseases of the Heart, Soho-square, London.

JACOB, ERNEST H., M.A., M.D. Oxon., has been appointed Physician to the General Infirmary at Leeds.

JOHNSTON, J. MCC., M.B., C.M. Glasg., has been appointed Medical Officer by the City of Glasgow Parochial Board.

LANE, J. ERNEST, F.R.C.S., has been appointed Surgeon to the In-patients, London Lock Hospital.

LAZENBY, F. H., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Sanitary District of the Clitheroe Union.

MARSH, F., F.R.C.S., has been appointed Assistant Surgeon to the Birmingham and Midland Ear and Throat Hospital.

MASON, GEORGE A., M.A., M.B., B.C. Cantab., has been appointed House Physician to the City of London Hospital for Diseases of the Chest, Victoria-park.

MORT, HERBERT BROWNLOW, L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Physician to the Governesses' Home, Southport, vice Wm. Mort, M.D., resigned.

MULVANY, JOHN, M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the Cottage Hospital, Walsall, vice Kenneth W. Poole, resigned.

NETTLE, WM., M.R.C.S., has been appointed Medical Officer of Health for the Liskeard Urban Sanitary District of the Liskeard Union, vice Hingston, resigned.

RUDD, C. F., M.R.C.S., has been appointed Medical Officer for the Teignmouth Sanitary District of the Newton Abbott Union.

SAMUELSON, GERALD S., M.B. Edin., has been appointed Medical Officer to the Gundagai District Hospital, N.S.W.

SHARP, P., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Broughton Sanitary District of the Newark Union.

SMYTH, R. V. B., M.D. Dub., B.Ch., L.M.R.C.P. Irel., has been appointed Medical Officer for the South Mims Court Cecil, Marquis of Salisbury, A.O.F.

STREATFIELD, PERCY WM., L.R.C.P. Lond., M.R.C.S.E., has been appointed Medical Officer for the Sixth District, and Public Vaccinator for the Sixth and Seventh Districts of the Tunbridge Union.

WARNER, E. H., M.D., C.M. Edin., has been appointed Medical Officer for the St. Philip's South Sanitary District of the Barton Regis Union,

WILLIAMSON, CHAS. F., M.R.C.S., L.R.C.P. Lond., L.S.A., has been appointed Medical Officer and Public Vaccinator for the Third District of the Reigate Union, vice Jas. W. G. Farwell, deceased.

YUILL, JOHN L., M.B., C.M. Glasg., has been appointed House Surgeon to the Monkwearmouth and Southwick Hospital, Sunderland.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

ALTON UNION.—Medical Officer and Public Vaccinator. Salary as Medical Officer £110 per annum, with the usual extra fees. The Public Vaccinator is paid by fees of 2s. for each case at his residence, and 3s. for each case at the out stations. (Apply to Mr. M. H. Moss, Alton, Hants).

PLYMOUTH BOROUGH ASYLUM, Blackadon, Ivybridge, Devon.—Assistant Medical Officer. Salary £125 per annum, with quarters, board, and washing.

ROTHERHAM HOSPITAL.—Assistant House Surgeon for six months. Rooms, commons (exclusive of alcoholic drinks), and washing will be provided in the hospital in lieu of salary.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C.—Honorary Assistant Medical Officer for Casualty work to the Convalescent Branch, "Bellgarth," Temple Fortune, Finchley-road, N.W.

SUSSEX COUNTY HOSPITAL, Brighton.—Assistant House Surgeon. Salary not exceeding £30 per annum, and board and residence in the hospital.

WEST NORFOLK AND LYNN HOSPITAL, King's Lynn.—House Surgeon and Secretary. Salary £80 per annum, rising to £100. Board, lodging, and washing in the hospital.

WESTERN GENERAL DISPENSARY, Marylebone-road, N.W.—Senior House Surgeon. Salary £70 per annum, with board and apartments.

Births, Marriages, and Deaths.

BIRTHS.

BARCROFT.—On April 15th, at Amesbury, Wilts, the wife of Penrose John Barcroft, F.R.C.S.I., of a son.

BLOOD.—On April 11th, at Devonshire-road, Birkenhead, the wife of Surgeon-Major J. Blood, Bengal Medical Service (half-pay), of a daughter.

BRADSHAW.—On April 15th, at Clarence House, Everton-road, Liverpool, the wife of J. C. Bradshaw, L.R.C.P., &c., of a daughter.

BUNTING.—On April 12th, at Edensor, Southsea, the wife of R. O. Bunting, Surgeon and L.D.S., of a daughter (Dorothy Elsie).

GODDARD.—On April 7th, at Wembley, Harrow, the wife of Charles E. Goddard, L.R.C.P. Lond., M.R.C.S., of a daughter.

HARDYMAN.—On April 18th, at 43, Great Pulteney-street, Bath, the wife of George Hardyman, M.B., of a daughter.

MORTIMER.—On April 18th, at Horley, Surrey, the wife of J. D. Mortimer, M.B., F.R.C.S., of a daughter.

RELTON.—On April 15th, at Rugby, the wife of Bernard Relton, M.R.C.S., of a son.

VERNON.—On April 15th, at Drayton, Christchurch-road, Boscombe, Bournemouth, the wife of A. Heygate Vernon, F.R.C.S., of a son.

WELSH.—On April 17th, at Biggleswade, Beds., the wife of Dr. R. C. Welsh, of a daughter.

WHITCOMBE.—On April 8th, at Westerham, Kent, the wife of C. H. Whitcombe, F.R.C.S. Ed., of a daughter.

WILSON.—On April 12th, at Sparrows Herne, Bushey, Herts, the wife of Daniel Wilson, M.D., of a daughter.

MARRIAGES.

ABBOTT—ROBINSON.—On April 14th, at Bedford Chapel, Bloomsbury, W.C., by the Rev. S. A. Brooke, M.A., George Abbott, M.R.C.S., of the Pantiles, Tunbridge Wells, and 17, Upper Wimpole street, W., to Edith, eldest daughter of H. P. Robinson, Winwood, Tunbridge Wells.

BRIGGS—HALL.—On April 20th, at Prescot Parish Church, by the Rev. Harry Mitchell, Vicar, Henry Briggs, M.B., F.R.C.S. Eng., of 3, Rodney-street, Liverpool, to Annie Rosalie, eldest daughter of Egerton Francis Hall, M.D., The Ash Trees, Prescot.

BUTLER—TAYLOR.—On April 6th, at the Congregational Church, Peterhead, N.B., William Butler, M.B., C.M., Harlesden, London, to Isobel Anne, youngest daughter of W. L. Taylor.

GLASSINGTON—THOMAS.—On April 18th, at Holy Trinity, Brompton, Chas. W. Glassington, M.R.C.S., L.D.S., to Louisa Anna Catharina Thomas, elder daughter of the late Frederick Thomas, of Brompton-road.

KEAY—JOHNSTON.—On April 19th, at St. Thomas's Church, Stockport, John Keay, of Heaton Norris, Surgeon, to Edith, only daughter of John Watkins Johnston, of Stockport, Solicitor.

JOHNSTONE—FLEMING.—On April 6th, at Holy Trinity Church, Edinburgh, John Carlyle Johnstone, M.D., Melrose, to Catherine Annie, youngest daughter of Andrew Fleming, M.D., Deputy-Surgeon-General, Retired List, H.M. Indian Army (Bengal).

JOHNSTONE—HUDSON.—On April 18th, at the Church of St. Mary Abbot, Kensington, James Johnstone, B.A., M.B., C.M., F.R.C.S., son of the late Rev. Wm. Johnstone, M.A., Port Chalmers, New Zealand, to Rose Ethel, youngest daughter of W. L. Hudson, Esq., late of Manchester.

PARSONS—ALLAN.—On April 19th, at St. James's, Weybridge, Surrey, Dr. Frederic William Parsons, of Wimbledon, to Mary, fourth daughter of the late J. B. Allan, of Eddlewood, Weybridge.

RUSSELL—THORNBURY.—On April 19th, at Saint Jude's, Gray's-inn-road, by the Rev. W. D. Fanshawe, Vicar, William Fox Russell, M.B. &c., Holyhead, second son of John Russell, J.P., Glenview, co. Limerick, to Ethel Maria Thornbury, elder daughter of the late W. H. Thornbury, Natal, and granddaughter of the late Colonel Thornbury and Henry Collins, St. Bees.

DEATHS.

DODD.—On April 12th, at Westbourne-terrace-road, John Dodd, Esq., M.R.C.S., formerly of Portman-street, Portman-square, in his 89th year.

DUNN.—On April 17th, at the Torrs, Crich, Derbyshire, Christopher Blencowe Noble Dunn, M.R.C.S. Eng., eldest son of the Rev. Christopher Blencowe Dunn, of Howden, Yorkshire. Born August 23rd, 1836. Died April 13th (Easter Day), 1892.

WALKER.—On April 14th, at Spondon, near Derby, Benjamin Walker, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., aged 48 years.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, April 25.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Tuesday, Wednesday, Friday, and Saturday at the same hour.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations daily at 10 A.M.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.

UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. J. Kent Spender (Bath): The Rarer Complications of Rheumatoid Arthritis.—Sir Dyce Duckworth: Infective Endocarditis of the Right Side of the Heart.

Tuesday, April 26.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.; Fridays and Saturdays at the same hour.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same day, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Professor Bonney: The Sculpturing of Britain—its Later Stages. (The Tyndall Lectures.)

ROYAL STATISTICAL SOCIETY (Lecture Theatre, Museum of Practical Geology, 28, Jermyn-st., S.W.).—7.45 P.M. Mr. R. Henry Rew: An Inquiry into the Statistics of the Production and Consumption of Milk and Milk Products in Great Britain.

SOCIETY OF ARTS.—8 P.M. Sir Edward Braddon: Australasia—its Progress and Resources.

Wednesday, April 27.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1.30 P.M.; Saturdays, 2 P.M. Obstetrical Operations, Thursdays, 2 P.M.

CHARING-CROSS HOSPITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.30 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.

HUNTERIAN SOCIETY (London Institution).—8.30 P.M. Mr. Hope Grant (with Dr. Snell) will show a case of Hydatid Membranes passed by Urethra and Rectum from Spleen after Fifteen Years.—Mr. H. W. Denton Cardew: On the Electrical Treatment of Graves's Disease.—Mr. W. Jang: On the Treatment of some of the External Diseases of the Eye.

SOCIETY OF ARTS.—8 P.M. Professor Robert Wallace: Egyptian Agriculture.

Thursday, April 28.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.

ROYAL INSTITUTION.—3 P.M. Professor Dewar: The Chemistry of Gases.

SOCIETY OF ARTS.—4.30 P.M. Sir William Wedderburn: Reorganisation of Agricultural Credit in India.

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square).—8.30 P.M. Mr. John W. Taylor (Birmingham): Some cases of Ectopic Gestation.—Mr. Berryman Jessett: Kyphotomy in a Woman with One Kidney

Friday, April 29.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

ADVERTISING PRACTITIONERS.

WE direct the attention of the profession to the following advertisements, not that they may be imitated. They occur in an advertising sheet of Huddersfield, and they candidly appeal to the public as the other advertisers do. It is discouraging to see graduates of universities using such methods.

"*Notice.*—Dr. Milligan begs to intimate to his patients that Dr. James Laird has succeeded him in his Surgery at 29, St. Peter's-street. In future Dr. Milligan's hours for consultation at South Parade (Surgery Entrance, corner Manchester-road) will be—Morning 9–9.45; Afternoon 2.30–3.30; Evening 6–8."

"*Notice.*—Dr. J. Laird wishes to inform the public of Huddersfield and District that he has succeeded to the practice till lately carried on by Dr. Milligan, at 29, St. Peter's-st. Dr. Laird's consultation hours will be—Morning 10–11; Evening 6–8; Sunday Evening 8–9. Dr. Milligan carries on his practice as usual at South Parade."

Mr. G. M. Polsue.—The important case referred to by our correspondent has already been noticed in our columns.

MEDICAL PRACTICE IN SOUTH CALIFORNIA.

To the Editors of THE LANCET.

SIRS,—Can you favour me with your advice as to how to get information regarding medical practice in South California? I am a young graduate, and I desire to make my home there in some growing health resort in a good farming part of the State. Where is suitable information regarding prospects, suitable openings, etc., to be obtained?

I remain, Sirs, yours faithfully,

[illegible]

April 19th, 1892.

A PIN SWALLOWED AND DISCHARGED BY [illegible]

DR. BOJANOWSKI mentions in a [illegible] the case of a little boy of between three and four years of age [illegible] pin, and for nearly half a year [illegible] extremities and [illegible] in time, however, he suffered [illegible]

INFLAMMABLE TONGUE DEPRESSORS.

WE learn from a correspondent that the proprietors of a certain beef essence are distributing gratis among the profession, as an advertisement, tongue depressors having the appearance of ivory, with the name of their preparation stamped on the handle. This instrument consists of the same material as the "inflammable buttons" lately referred to in THE LANCET, and might prove a dangerous aid to operation, especially in applying the actual or galvanic cautery to the throat or mouth. When touched with a glowing coal it instantly ignites and burns with a fierce flame leaving almost no ash.

Alpha.—The answer to the first question is in the negative. Answers to the various questions regarding the incidence of postage under the Infectious Diseases (Notification) Act appeared in THE LANCET of March 26th, page 713.

SCHOOL INFIRMARIES AND SANATORIA.

To the Editors of THE LANCET.

SIRS,—Can you tell me whether, as regards public schools, there is any fixed percentage of room for sick boys as compared with the total number of scholars? In some schools of which I am medical officer there are 100 boys, and only room for ten when ill. Fever or diphtheria cases are at once removed to the London Fever Hospital. My contention is that it is not enough. With an outbreak of measles, for instance, out of 100 boys there would surely be more than ten ill at once. The sick rooms are not detached from the main building. Do you think the amount of room is sufficient? Or, rather, ought there not to be accommodation for at least twenty boys? There are also four masters living on the premises, and one or more of these might be ill. I should very much like to know whether there is any customary amount of accommodation for the sick.—I am, Sirs, yours truly,

April 13th, 1892. W. G. G.

*** Our correspondent should obtain a copy of the pamphlet entitled "The Construction and Maintenance of School Infirmaries and Sanatoria," edited by Dr. Sheely and Dr. H. Alder-Smith, and published by Messrs. Churchill. The pamphlet is prepared by the Council of the Medical Officers of Schools Association. For the information of those of our readers who may be situated similarly to our correspondent we may add that the accommodation would be influenced by the ages and social status of the boys and other considerations. According to the pamphlet, 20 per cent. of accommodation ought to be provided for infectious diseases; but if that were done in large schools the sanatorium would in some cases be half as large as the school itself, which would be too costly. In the case of a large outbreak of measles or of influenza extra wards must be used. If fifty or sixty cases occurred in a large school, the spread of the epidemic could not be prevented, and hence ordinary wards could be utilised, or even a large iron building for an emergency. In a school of 100 boys there ought to be five beds at least for ordinary cases, and ten in a sanatorium, with another ten elsewhere in case of need. This is all that would be required for scarlet fever &c.; for if ten cases were to occur the school ought to be broken up. But in the case of measles twenty or thirty cases might be provided for. If masters have to be treated in the sanatorium, then more room would be required.—ED. L.

ARE THE PRESENT ROAD-LEVEL SEWER VENTILATORS EFFECTUAL?

To the Editors of THE LANCET.

SIRS,—I have before now gone into the question as to whether road-level ventilators are conducive to the public health; but there is another point of certainly equal importance which requires consideration, and that is as to their efficiency. Now, if anyone will take the trouble to inspect a series of these in any thoroughfare where there is a heavy vehicular traffic, he will find the greater part of the gratings completely filled with mud, and under these circumstances they can scarcely be said to be effectual in their operation. I would therefore say that both in point of safety and efficiency we have not yet arrived at the best method of ventilating our main sewers.

I am, Sirs, your obedient servant,

Surbiton, April, 1892. F. P. ATKINSON.

MADAME HENRI GREVILLE AND M. PASTEUR.

MADAME GREVILLE is well known not only as one of the most brilliant of French novelists, but also as an acute observer of the manners and customs of the people among whom she has journeyed and sojourned. M. Pasteur has in a letter given public expression to his indebtedness to her for her description of the *modus operandi* of the Muscovites in cases of hydrophobia. She had watched their treatment of such cases—immersion of the patient in a vapour bath raised to the highest possible temperature. The success of this seemingly desperate remedy was such as to cause her to bring it under the notice of M Pasteur long before he entered on his special studies in hydrophobia—studies in which Madame Greville's experiences, as he acknowledges, quickened his interest.

FRENCH PRISONS AND THEIR SANITATION.

DOCUMENTS lately made *publici juris* give a sombre picture of life in the prisons—especially the Parisian prisons—of France. It is only of late years that these institutions have been specially built for their purpose, the general rule having been to "adapt" some old edifice—sometimes a convent, sometimes an almshouse—for the reception of convicts. Take, for instance, the St. Pélagie, next to the Conciergerie the oldest prison in Paris. A convent in 1665, it was long a debtor's prison, and is now used as a penitentiary for those whose detention does not exceed twelve months. The besetting fault of French prisons—overcrowding—is seen at its worst in such a building, constructed on seventeenth-century lines, in defiance of what is now known as hygienic science, and, as a result, saturated to its very basement with fever germs. Disinfection, practised from time to time, remains powerless to reduce the prevalence of typhoid fever within its walls, no other prison in France—a large order!—contributing more inmates to the infirmary. Its 700 prisoners are distributed over eighty cells, from five to ten beds being the average in each dormitory. The young and comparatively innocent convict is thrown into closest contact with the inveterate jail-bird, by whom he is initiated in crime, and comes out an accomplished thief or burglar—a fact which explains the appalling return showing that, in 1889, out of 20,000 malefactors more than 16,000 were below twenty years of age. The solitary confinement practised in the great model prison of Paris, the Mazas, has been followed by evils which, in the case of a mercurial people like the French, are so pronounced as to engage the serious consideration of prison reformers. So terrible is the seclusion, so hopeless all chance of escape, that, rather than get committed to the Mazas, the French criminal classes endeavour, by aggravation of their offences, to incur the nominally more severe, but in their eyes more tolerable, punishment of transportation to New Caledonia, with its open-air life and its companionship, to say nothing of the possibility of giving the warders the slip. Detention in the Mazas is sooner or later followed by suicide among a vast proportion of its inmates, insomuch that one entire section of it is specially organised for those whose proclivities to self-murder are suspected. The Dépôt de Mendicité at St. Denis was lately destroyed, not a moment too soon, and replaced by another building less in the nature of a fever preserve. For forty-seven years the Dépôt had existed over a sewer of the old-fashioned type, which exhaled its effluvia among the overcrowded inmates.

L.S.A. Lond. & Dub. will see that we have not overlooked the question which he raises.

SPRAY PRODUCERS WITH CHECK ACTION.

To the Editors of THE LANCET.

SIRS,—Will you allow me to explain the check action I have used for seventeen years? I hold the bottle in the left hand, and before using the bellows I get the tubing between my index finger (or middle) and thumb. When I want to moderate or stop the spray, I use pressure of my fingers to bring about the effect. No ingenuity, no novelty, and no instrumentality are all I claim for the above plan.

I am, Sirs, yours faithfully,

April 14th, 1892. POTESTAS.

TAXATION OF GAMBLING.

THE authorities of Paris, according to the *St. James's Gazette*, unable to prevent gambling, have hit on the plan of taxing gaming stakes for the benefit of the Assistance Publique. The result is that a considerable sum has just been applied to the purpose of constructing a new consumption hospital, and a further amount partly to like institutions, and partly to the furtherance of the revaccination campaign under the auspices of the Paris Academy of Medicine.

Viator.—It is both customary and reasonable to make an extra charge when more than one member of a family is seen.

"MICROSCOPICAL WORK."

WE have received several communications from gentlemen offering their services in the direction indicated by "M.R.C.S." in his letter of last week, under the above heading. It is obvious that we cannot publish them, as they would necessarily savour of the nature of advertisements. Perhaps our correspondent will furnish us with an address at which these gentlemen may communicate with him.

Anxious.—We must refer our correspondent to the Students' Number of THE LANCET, published on Sept. 6th last.

SURGEON-CAPTAIN G. E. HALE, D.S.O.

THE name of the officer of the Medical Staff on whom the Distinguished Service Order has been conferred for his gallant services in the field operations in Burmah is Surgeon-Captain G. E. *Hale* (not "Hare," as was erroneously printed in our annotation last week).

The Publisher cannot hold himself responsible for the return of testimonials &c. sent to the office in reply to advertisements; copies only should be forwarded.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Office letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 3 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements to ensure insertion the same week should be delivered at the Office not later than Wednesday, [illegible] in advance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Letters for Postal Transmission may be obtained of the Publisher, to whom all letters [illegible] should be addressed.

RESTORATIVE FOODS.

The Kepler Extract of Malt.

Kepler Extract of Malt supplied to the Medical Profession in bottles, containing ¾-lb. and 1½-lb., at 1s. 8d. and 3s. 0d. Retail prices, 2s. 6d. and 4s.

The Kepler Extract of Malt may be obtained from all chemists.

These preparations are palatable and easily digested.

They assist the digestion of farinaceous foods.

They promote the thorough assimilation of starch.

They are ideal foods in scrofula, rickets, and consumption.

They are recognised as highly nutritious foods.

The Kepler Solution of Cod Liver Oil is readily taken by children and invalids who are unable to take the oil itself, or in emulsion.

The Kepler Solution does not cause eructations or excite nausea.

When there is rapid tissue metamorphosis the Kepler Solution of Cod Liver Oil is an admirable fuel for the system, maintaining nutrition and protecting the tissues against the ravages of the tubercle bacilli.

On account of the large amount of *diastase* present, the Kepler Extract of Malt is a useful digestant, it is soothing to the stomach and intestines, and tends to maintain a healthy condition of the digestive functions.

When the Kepler Solution of Cod Liver Oil is ingested it acts as a soothing agent. In irritable conditions of the gastric mucous membrane the oil remains in solution in the Malt Extract until it passes through the pylorus and is then readily digested and completely assimilated.

Many foods are obtainable which are recommended on account of the *nitrogenous* matter contained in them. This is not the case with the Kepler preparations. We do not introduce it to the medical profession as a vegetable beef-tea, because the *real* article is superior to any imitation possible. Although the Kepler preparations contain as large a percentage of nitrogenous material as any similar preparation, they are recommended chiefly as an abundant source of carbo-hydrates, and in the case of the Kepler Solution of carbo-hydrates and assimilable fat.

The Kepler Solution of Cod Liver Oil in Extract of Malt.

Kepler Solution of Cod Liver Oil in Extract of Malt supplied to the Medical Profession in bottles, containing ¾-lb. and 1½-lb., at 1s. 8d. and 3s. Retail prices, 2s. 6d. and 4s.

This preparation is stocked by all respectable dispensing chemists.

The BRITISH MED. JOUR. reports:—"We can recommend the Kepler Malt Extract. Being prepared at a very low temperature, its qualities are not deteriorated or its flavour spoiled. It is very favourably spoken of by physicians, both in respect to its nutritive and digestive properties, and as being of very agreeable flavour."

The MEDICAL TIMES AND GAZETTE says: "By far the best."

The BRITISH MEDICAL JOURNAL reports: The Kepler Solution "is an ideal form for the administration of fat." .... "The production of a Solution of Cod Liver Oil in Malt Extract is a great advance, and marks an epoch in the history of rational therapeutics."

The MEDICAL PRESS AND CIRCULAR reports: "It is the most palatable and easily digested of any form of Cod Liver Oil"

THE LANCET says: "This preparation is known as the Kepler Solution of Cod Liver Oil. .... Its superiority as a therapeutic agent, especially in cases of wasting disease, is obvious."

THE LANCET reported upon Kepler Extract of Malt in 1881 as follows:—"It is the best known and, in this country, the largest used Extract of Malt. It is as distinct an advance in therapeutics as was the introduction of cod liver oil. It is one of our best nutritive and digestive agents for chronic dyspepsia, and is undoubtedly useful in consumption and other wasting diseases."

Again, the same journal reports in 1891 as follows:—"It is some time now since we had occasion to examine the well-known and much-used KEPLER EXTRACT OF MALT. Messrs. Burroughs, Wellcome, & Co. evidently keep pace with the newest scientific facts, which every day contribute towards making this kind of preparation perfect."

The MEDICAL PRESS AND CIRCULAR says: "The Kepler Solution is the most palatable and easily digested of any form of cod liver oil."

BURROUGHS, WELLCOME, & CO., SNOW HILL BUILDINGS, LONDON, E.C.,

Will be happy to supply Trial Specimens to Medical Men free on request.

H. K. LEWIS'S PUBLICATIONS.

Ready this day, royal 8vo, with 130 Coloured Illustrations, 31s. 6d.

A TEXT-BOOK OF MORBID HISTOLOGY.

By RUBERT BOYCE, M.B., M.R.C.S.,

Assistant Professor of Pathology in University College, London.

With an Introduction by Prof. VICTOR HORSLEY.

A short account of the more marked histological changes in disease, designed as a practical and theoretical introduction to the higher branches of pathological morphology. The work includes a special and a general part, treating of the commoner histological methods, inflammations, congenital and acquired tumours, degenerations, the more important tissue reactions in mycotic and zooparasitical diseases, and the diseases of the separate systems; an appendix with the recent literature of each subject; and an introductory preface by Prof. Horsley. It is fully illustrated with 130 original coloured micro-photographic illustrations made specially for the work.

Now ready, the EIGHTH Edition, in One Volume of over 1000 pages, with Illustrations, large 8vo, 21s.

A HANDBOOK OF THE THEORY AND PRACTICE OF MEDICINE.

By FREDERICK T. ROBERTS, M.D., B.Sc., F.R.C.P.,

Examiner in Medicine at the University of London and for the Conjoint Board; Professor of Therapeutics and of Clinical Medicine in University College; Physician to University College Hospital and to the Brompton Hospital, &c.

"The amount of information in this book is, for its size, enormous. .... The book seems to be thoroughly trustworthy, and those who read it may be sure that the views put before them are not the fanciful notions of the few, but the well-considered and generally adopted ideas of our leading scientific practitioners. .... Abounds in information supplied in a thoroughly systematic manner."—THE LANCET.

By the same Author, Second Edition, Revised in accordance with the last British Pharmacopœia, fcap. 8vo, 7s. 6d.

THE OFFICINAL MATERIA MEDICA,

INCLUDING THE ADDITIONS MADE TO THE BRITISH PHARMACOPŒIA, 1890.

Also, fcap. 8vo, cloth, 1s., post free.

Notes on The Additions made to the British Pharmacopœia, 1890.

The TWELFTH EDITION, demy 8vo, 15s.

A Handbook of Therapeutics. By Sydney Ringer, M.D., F.R.S., Professor of

Principles and Practice of Medicine in University College, Physician to University College Hospital, &c.

"It is unquestionably the ablest work on Therapeutics which we possess in our language, and one which should be carefully perused, not only by students, but also by practitioners. Having on several occasions spoken most favourably of Professor Ringer's work, it is sufficient to draw the attention of our readers to this new edition which has just been issued. .... Ringer's Therapeutics is a work so well known that it needs no commendation from us to ensure it a wide circulation."—EDINBURGH MEDICAL JOURNAL.

Now ready, SIXTH Edition, Revised, crown 8vo, 9s.

Elements of Practical Medicine. By Alfred H. Carter, M.D. Lond., F.R.C.P. Lond.,

Physician to the Queen's Hospital, Birmingham; Professor of Therapeutics in Queen's College, Birmingham, &c.

"That this book is much appreciated by the student is evident from the regularity with which fresh editions make their appearance. It merits its popularity. It is thoroughly practical in its aim and sound in therapeutics."—THE LANCET.

"The fact that this well-known handbook of medicine has now reached its sixth edition is good evidence of its merit, and of the fact that it supplies a felt want."—EDINBURGH MEDICAL JOURNAL.

Third Edition, copiously Illustrated, with Coloured Plates and Engravings embodied in the text, demy 8vo, 21s.

Manual of Bacteriology: being an Introduction to Practical Bacteriology. Revised

and considerably Enlarged. By EDGAR M. CROOKSHANK, M.B., F.R.M.S.

"The work is one which in every respect deserves, and will doubtless receive, a foremost place in scientific literature."—THE LANCET.

"Every subject is profusely illustrated, and most of the coloured illustrations, both those of cultivations and of microscopical specimens, attain a very high degree of excellence."—BRITISH MEDICAL JOURNAL.

Now ready, Third Edition, with Illustrations, crown 8vo, 10s. 6d.

A Practical Text-book of the Diseases of Women. By Arthur H. N. Lewers,

M.D. Lond., M.R.C.P. Lond., Assistant Obstetric Physician to the London Hospital; Examiner in Midwifery and Diseases of Women to the Society of Apothecaries of London. [*Lewis's Practical Series.*

"We have read it with much interest, and can recommend it as a most excellent manual, thoroughly practical, carefully written, and up to the latest advances in this most progressive branch of medicine."—THE LANCET.

"It is well suited to the needs of the students. .... Altogether praiseworthy are the opening chapters on the proper methods for investigating cases where disease of the female genitals is suspected to exist, and on normal and abnormal physiological phenomena in women."—BRITISH MEDICAL JOURNAL.

Crown 8vo, 8s. 6d.

Elements of Materia Medica and Pharmacy.

MACY. Including the New Official Remedies, B.P., 1890. With Special Chapters on Doses, Strengths, and Incompatibles. By ALFRED W. GERRARD, F.C.S., Examiner to the Pharmaceutical Society; Teacher of Pharmacy and Demonstrator of Materia Medica to University College Hospital, &c.

Crown 8vo, 3s. 6d.

The Mechanism of the Circulation of the

BLOOD through ORGANICALLY DISEASED HEARTS. By HERBERT DAVIES, M.D., F.R.C.P., late Consulting Physician to the London Hospital. Edited by ARTHUR TEMPLER DAVIES, B.A., M.D. Cantab., M.R.C.P., Physician to the Royal Hospital for Diseases of the Chest.

Now ready, Second Edition, with Plates and Wood Engravings, demy 8vo, 12s. 6d.

Diseases of the Nose and its Accessory

CAVITIES. By W. SPENCER WATSON, F.R.C.S. Eng., M.B. Lond., Surgeon to the Throat Department of the Great Northern Central Hospital, &c.

By the same Author, in preparation,

Diseases of the Lachrymal Passages.

Just published, crown 8vo, with Illustrations, 2s. 6d. net, post free 2s. 8d.

Outlines of Practical Physiological

CHEMISTRY. By F. CHARLES LARKIN, F.R.C.S. Eng., &c., late Assistant Lecturer in Physiology in University College, Liverpool; and RANDLE LEIGH, M.B., B.Sc. Lond., &c., Senior Demonstrator of Physiology in University College, Liverpool.

Second Edition, 12mo, 1s. net, post free 1s. 1d.

Notes on the Examination of the Sputum,

VOMIT, FÆCES, URINE, and BLOOD. By SIDNEY COUPLAND, M.D., F.R.C.P., Physician to the Middlesex Hospital, Examiner in Medicine at the Examining Board for England.

Crown 8vo, 5s.

Sprains; their Consequences and Treat-

MENT. By C. W. HANSELL MOULLIN, M.A., M.D. Oxon., F.R.C.S., Surgeon to the London Hospital.

Now ready, fcap. 8vo, 2s.

Practical Chemistry for Medical Students,

required at the First Examination of the Conjoint Examining Board in England. By SAMUEL RIDEAL, D.Sc. Lond., F.I.C., F.C.S., F.G.S., Fellow of University College, London; late Lecturer on Chemistry and Physics at St. George's Hospital Medical School.

Lumleian Lectures

ON

CERTAIN POINTS IN THE ETIOLOGY OF DISEASE.

Delivered at the Royal College of Physicians on March 31st and April 5th and 7th, 1892,

BY P. H. PYE-SMITH, M.D., F.R.S.

LECTURE III.

MR. PRESIDENT AND GENTLEMEN,—We have now passed in review the general causes of disease—or, to use a term more consonant with our imperfect knowledge, the conditions under which diseases arise,—external and internal, exciting and predisposing, natural and accidental. I had prepared a series of notes on the etiology of the more important diseases, to serve partly as examples of the application of the etiological rules before discussed, partly as instances on an induction from which those rules have been, or may be, established. But the time which remains at my disposal is far too short for so extended a survey, and the data are at present too few and too unconnected to be otherwise than dry and tedious. I will, therefore, with your permission, occupy the present lecture with a particular consideration of a few only of the diseases most important and interesting from an etiological point of view. We will begin with a group of diseases of the nervous system, which includes one of the most common and obscure in its origin—chorea.

Spasmodic neuroses in general.—The etiology of the vast, and still in many places obscure, domain of diseases of the nervous system is at present an almost unexplored path. Even organic affections of the brain and spinal cord are in many cases so undetermined in their symptoms that those who have the greatest experience are most diffident of their diagnosis until it has been confirmed by a necropsy; while for functional neuroses we have not this safe, even though narrow, foundation for etiological theories.

Nothing but error and confusion can result from speaking of "nervous diseases" in general as inherited, as incident to a particular climate or occupation, or sex or age, or to ascribe them to intemperance, hard work, or any other cause; for the group is not a natural one, and can therefore have no common etiology. The most obvious, frequent, and recognisable clinical disease of the brain (apoplexy followed by hemiplegia) is pathologically disease of the heart or bloodvessels. In other cases cerebral symptoms are due to tumours as accidentally present in the brain, as a bullet or a crowbar; cerebral abscess is never "nervous" in origin, but is traumatic or secondary to suppuration elsewhere; meningitis is tubercular, traumatic, or infective, but never "nervous"; and "phrenitis," or primary congestion of the brain, does not exist. Among diseases of the spinal cord, we know that a large number of cases of paraplegia are due to tubercular caries, and a smaller number to malignant disease of the vertebræ. And so of the large and obscure group of functional neuroses, we must remember that if we knew their true pathology they might prove to be as unconnected as the convulsions of uræmia are with those caused by a cerebral tumour.

Some of them may be described as exaggerations of individual eccentricities, of bad habits, involuntary gestures, and tricks of movement which have never been repressed by education. It is remarkable how often among the lower orders the natural beauty of a child's face is marred by its continual grimaces. An inexperienced speaker will betray his nervousness or enforce his conviction by twenty odd movements and ungainly gestures which, if they became fixed and habitual, might fairly be called spasmodic neuroses. Some of them are emotional outbursts, others are consensual movements dependent upon the law of irradiation by which a powerful motor stimulus is apt to overflow beyond its intended channels. To the first group belong the smiles, the tears, the shuddering, and the involuntary applause of the spectator of a drama or of the auditor of an oration. To the second, movements of the face, the hands, the arms, and the whole body which accompany the words of a public speaker. These, when properly restrained and disciplined, form half the power and the charm of acting or of oratory; but they have their origin in the uncouth movements of a clown at a fair, or of an illiterate person painfully composing a letter. These involuntary, emotional, or consensual movements may, under certain circumstances, be developed into paroxysmal neuroses—on the one hand into spasmodic tic, on the other into hysterical convulsions; and in accordance with this supposed origin is the asserted fact that such functional disorders are more common in France and Italy than among the less emotional, less demonstrative, population of Great Britain.

Another kind of local spasmodic neuroses have a very different etiology. I refer to the group of nervous disorders named by Dr. Weir Mitchell "functional spasms," a phrase which does not refer to their having no anatomical basis, but to their following the too prolonged exertion of some motor function. Dr. Gowers calls them "occupation-neuroses," and in Germany they bear the neat and convenient designation, "Beschaftigungsneurosen," translated (without much sense of humour) as "professional spasms." Perhaps the phrase "fatigue spasms" is more significant and convenient than any other. The kind of cramp or tonic spasm following the over-use of muscles in a particular manœuvre includes the lock-spasm of watchmakers, of telegraph workers, and of milkmaids, and other effects of a habitual handicraft. Saltatorial spasms, eclampsia nutans, malleation, spasmus nictitans, writer's cramp, and the corresponding affection which sometimes attacks musicians are all etiologically related, for their origin can, in most instances, be traced to too constant exercise of the same set of muscles.

A distinct etiological group of spasmodic neuroses is almost confined to children, and more common in boys than in girls; it is closely related to rickets. Tetany or tetanilla carpopedal contractions, trismus neonatorum, and laryngismus stridulus, these may all be regarded as exaggerated and perverted reflex spasms occurring when the higher centres have not attained or have lost their inhibiting action over the spinal system. Their relation to one another and to rickets has been well brought out by Dr. Cheadle, and the remarkable association of the latter disease with infantile convulsions and zonular cataract is one of the contributions to the true philosophy of disease which we owe to Mr. Hutchinson.

Another very remarkable spasmodic nervous disorder—that described by Dr. Thomsen in 1876, and since generally known by his name—has relations in more than one direction: first, with reflex spasms; secondly, with emotional spasms, of which stammering is the best example; and, thirdly, with hysterical convulsions. Its peculiar etiological note is its remarkable distribution in families. Like Friedreich's disease, it is not always hereditary, but occurs in brothers or sisters without being transmitted from or to the next generation. This lateral rather than vertical distribution may be sometimes observed in rheumatism, insanity, and other diseases of more or less hereditary character. It seems to point to an etiological condition which is not directly derived from either parent, but is the result of two strains combining.

Chorea.—This remarkable neurosis was first described by Sydenham, and hence became known abroad as "chorea anglorum," and also as "chorea minor," to distinguish it from the "chorea sancti Viti major," the dancing mania of the Middle Ages. Dr Sturges has well insisted upon the relation of chorea to the fidgetiness, and face pulling, and ugly tricks to which I have just referred as the physiological type of certain neuroses. If a healthy child could not fidget and grimace, the symptoms of chorea would not be what they are: this I fully admit. But this only means that the symptoms of disease have a physiological basis, and has, I think, no peculiar bearing on the etiology of chorea. A soldier does not feel a wound until the conflict is over; a mother does not know her hand is burnt until her child is saved from the fire; and if temporary anæsthesia was not thus producible in healthy persons under strong emotional excitement, we should not see the hemi anæsthesia of hysteria. If a child did not laugh and cry and struggle when tickled, it would not have the mechanism by which infantile convulsions and adult epilepsy are produced. Morbid agents can only act upon the pre-existing physiological machine. All pathological states—fever, delirium, dropsy, inflammation—are but perverted working of the healthy organism. A cough is a physiological reflex action, but bronchitis is a disease. We all carry with us every day and all day long the faculty of disease in the mechanism and the functions

Google

of health. Although, to return to the example before us, the grimaces of chorea are those of a restless child, and the most violent movement of its limbs is effected by the same nervous and muscular mechanism which produces the corresponding voluntary gestures, yet we do not, I think, find that this disease is more frequent in fidgety children than in others, while the definite beginning, the pathological associations, and the clinical course of chorea stamp it as a true disease.[1]

The most important points in its etiology are: First, its marked predilection for childhood, or the period between the completion of dentition and the establishment of puberty. Secondly, its greater prevalence in girls than in boys, and the still more decided prevalence of adult chorea among women.[2] One occasionally sees a delicate ill-developed youth who, having been choreic before puberty, will continue subject to the disease up to twenty or twenty-five, and I once saw genuine chorea with rheumatic and cardiac complications in a man as old as forty. But while such cases are rare exceptions, chorea is not uncommon in girls up to the age of eighteen or twenty, and has long been recognised either as reappearing or appearing for the first time in the pregnant or puerperal state. The cases of senile chorea which have been from time to time described, first by Graves, since by Charcot and other French writers, and in this country by Dr. Saundby,[3] belong, I venture to think, to a separate pathological group.

Next to its well-marked relations to sex and age, chorea is undoubtedly associated with rheumatism, using that word as a synonym for rheumatic fever. This connexion was first pointed out on the Continent by Professor Sée, but had long previously been recognised in England by Dr. Copland, by Hughes, by Bright, and by the elder Babbington, who stated in his lectures so far back as 1811 that chorea "often follows rheumatism, and that these two diseases often come on alternately."

The following are the figures arrived at by many independent observers. Professor Sée's were collected in the Hôpital des Enfans Malades at Paris. They come near in point of time (1850) to those of Dr. Hughes' first series (1846). Dr. Sturges' cases were his own patients at the Hospital for Children in Great Ormond-street; Dr. Donkin's cases were his out-patients at the Westminster Hospital; Dr. Goodhart's were his patients at the Evelina Hospital for Children; Dr. Stephen Mackenzie's were from the London Hospital. Dr. Herringham and Dr. Archibald Garrod each published particulars of eighty cases in the seventy-second volume of the Medical and Chirurgical Society's Transactions (1889) from his own out-patients. Then come 439 cases reported from various sources and put together by the Collective Investigation Committee of the British Medical Association—statistics compiled, and therefore not homogeneous, but noteworthy as being drawn from private cases. Lastly, we have 475 cases from Guy's Hospital; 162 collected from his own patients by the late Dr. Hughes, with the help of Dr. Burton Brown; and 313 published by myself, partly from my own hospital patients, partly from in-patients of the hospital (long subsequent to Dr. Hughes' death) collected for me by Surgeon-Major Manser and Dr. Halstead (now of Ramsgate).

Chorea associated with Acute Rheumatic Fever.

* Twenty-one cases had a clear history of rheumatic fever; fourteen had a history of pains and swelling of the joints.

[1] I have said that the grimaces of chorea are like those of health; but there is a difference which would enable one to distinguish one from the other if represented by a skilful painter. In the choreic child the eyes do not show the emotion which is simulated by the mouth; they have a blank [illegible] expression which makes the facial [illegible] those of [illegible] moved by strangers.

[illegible]

The connexion between the two diseases does not rest on statistics alone, but upon the anatomical fact of endocarditis being almost always present in fatal cases, since valvular disease in children is in the great majority of cases definitely connected with rheumatism. Further, chorea resembles rheumatism in two important clinical characters: in the age of the patients it attacks, and in the frequency of its recurrence. It is more difficult to determine the nature than the fact of the connexion. The evidence seems to me in favour of regarding rheumatism as a predisposing cause to chorea, not *vice versâ*, and the cardiac murmurs, the endocarditis, and the occasional pericarditis of chorea as due to rheumatic inflammation. That in children the joints are often so little affected and the pyrexia so slight may well account for a history of rheumatism being often absent. I have seen, not its previous occurrence, but its present existence unsuspected by the patient's mother.

Phthisis.—The wide and deeply interesting question of the etiology of pulmonary phthisis received new, but not altogether unexpected, light by Koch's brilliant discovery of the bacillus of tubercle. That this is a definite and recognisable species of microphyte is certain, and certain also that it is constantly present in lesions which are histologically tuberculous, and in particular in all forms of chronic caseous inflammation of both lungs, beginning at the apex, travelling downwards, and marked by the presence of lobular pneumonia, ulceration, bronchitis, pleurisy and cicatrisation, with the presence of grey and yellow granulations. In other words, all pulmonary phthisis is tuberculous, infective, and specific. This has, I take it, been conclusively proved; but herein we have only a part of the etiology of phthisis. Without the specific microbe, no phthisis. That we admit; but how many other conditions besides its presence are necessary to produce the disease? The importance of hereditary predisposition is surely put beyond question not only by our daily experience in practice, but by the results of life assurance. The local effects of pulmonary catarrh in preparing the soil for the reception of the invader is sufficiently proved by the undoubted existence of a large pathological group of cases caused by the irritation of solid mineral particles. Tubercle bacilli are found in the lungs of grinders and potters; but no one is so foolish as to throw away previously acquired experience, and deny that such trades cause phthisis. They cause phthisis (we must now believe) by producing pulmonary catarrh, and thus facilitating the entrance, survival, multiplication and successful establishment of the parasitic plant which causes the anatomical lesions of phthisis. Moreover, we learn from the almost universal prevalence of phthisis in certain trades that the "seeds of the disease" (i.e., the specific microbes) must be constantly present in the workshops, say, of Sheffield grinders; probably more common than in hospital wards, in health-resorts for the phthisical, or in ordinary dwelling-houses; so that these workrooms are, literally and not rhetorically, "hotbeds of disease." The sputum which one reckless, high-paid, short-lived, phthisical workman ejects from his ulcerated lungs dries and becomes dust. This is carried into the air passages of his neighbour, whose lungs have already begun to suffer from the particles of silica which he inhales: he has already been wounded, and now the wound is poisoned. Passing through the stomata of the air vesicles into the subjacent lymph spaces the virus is conveyed to the lymph glands, and then more gradually to distant organs.

So far seems clear, but many other etiological problems await solution. Why are young adults most subject to phthisis? Are they more exposed to the poison than old people? Or more liable to the precedent pulmonary catarrh? Or more apt to become abscess? Or is lymphatic absorption in them more active? Is catarrhal lobular pneumonia, particularly that which follows measles and pneumoconiosis, the only local preparation for the seed? Why is not bronchitis? Why is not lobar fibrous pneumonia? Do the bacilli themselves [illegible] as an irritant as well as an infective agent? Why does not the virus more often enter the body through [illegible] mucous membrane? Is it ever absorbed [illegible] wound? How does it gain access to [illegible] Does the [illegible]

of the very rapidly generalised tuberculosis of children with but slight caseation of lungs or lymph glands?

Pulmonary hæmorrhage has again and again been assumed to be a local cause of phthisis, and numberless cases to prove the point have been recorded. The most ancient is one mentioned by Herodotus (vii., 88). When the army of Xerxes was marching out of Sardis on its way to Thermopylæ and Platæa, a general of cavalry, Pharnuches by name, was riding at the head of his squadron. A dog ran between the legs of his horse, which reared and threw his rider. When lifted from the ground Pharnuches was spitting blood, and was left behind at Sardis, where he fell into a decline and died. This ancient doctrine, formally stated by Morton in the seventeenth century and by Cullen in the eighteenth, was revived in our own time by Professor v. Niemeyer, and made part of his now exploded theory of phthisis. By the light of our present knowledge may we not say that a healthy lung never, or very rarely, bleeds under any strain, and that if it should, such primary pulmonary hæmorrhage is innocuous, or at least never produces phthisis? Hæmoptysis is not uncommon in cardiac disease, particularly in cases of aortic and obstructive mitral lesions, and yet phthisis does not follow it; traumatic hæmoptysis, as by a fractured rib, does not go on to phthisis; and blood, when injected into the trachea of dogs, does not set up caseous changes in the lungs. May we not, then, assert, in harmony with clinical experience, that hæmoptysis (without disease of the heart and aorta, without purpura or injury), though often the first symptom is never the first event in a case of phthisis?

The association of phthisis with damp, undrained soil has been established by the classical researches of the late Dr. Bowditch in New England, and by Sir George Buchanan in the old country; and I cannot mention the name of the latter distinguished Fellow of this College without expressing the admiration which we all feel for his long and useful public services and his fidelity to the best traditions of scientific medicine. Does this observed association depend on the frequency of pulmonary catarrh in damp dwellings and ill-drained soils, or on a general depression of the resisting, protective, or, if you please, phagocytic properties of the tissues? Do starvation, anæmia, and other depressing influences act by diminishing the resistance of the patient, or by favouring a preliminary inflammation of the bronchioles? The same question applies to hereditary predisposition, and to the dyspepsia, anæmia, and loss of weight which often precede pulmonary symptoms.

Happily, even the briefest discussion of the etiology of phthisis would be incomplete without consideration of the antagonistic as well as the favouring conditions of the disease. Of the former we may first mention the patient's age. Though senile phthisis is not absolutely rare, it is relatively so; and most of the cases I have seen have been very chronic, sometimes relapses after recovery from phthisis in youth. A first successful invasion of the infection is certainly very rare after fifty. Again, phthisis in children, though very fatal when it occurs, is far less common than after puberty, and congenital phthisis is almost without example.

Free ventilation is certainly inimical to the lodgment of tubercle; no doubt partly by diluting the contagium, and partly by keeping up the appetite and power of resistance, since to a great extent we depend on the stomach to cure the lungs. A very cold and a very hot climate seem both antagonistic to phthisis; but, while the former is in some measure curative as well as prophylactic, the latter is rather injurious than beneficial when the malady is once established. Cold probably acts directly on the bacillus, which does not grow below a certain temperature, and heat perhaps by diminishing the predisposition offered by pulmonary catarrh. Carnivorous animals are much less liable to tubercle than herbivorous, but the rule is liable to exceptions, as in the case of goats; and there is no reason to suppose that among human beings vegetable feeders are less exposed to phthisis.

Finally, even in diseases themselves, we sometimes find allies against phthisis. Pulmonary emphysema appears to render the development of tubercle in the lungs more difficult; probably by diminishing the vascularity of the lung and by obstructing its lymphatic channels. It seems to be well established that so far from permanent cyanosis (and particularly that caused by congenital disease of the heart) being antagonistic to phthisis (as Rokitansky supposed), the subjects of congenital pulmonary ("dextro-sigmoid") stenosis are particularly liable to phthisis if they survive puberty. But cyanosis from disease of the right side of the heart with pulmonary anæmia is one thing, congestion of the lungs from disease of the left side of the heart is another; and I believe that mitral disease is really a negative factor in the etiology of phthisis. I have myself had two or three cases in which the destructive lesions in the lungs were apparently checked by cardiac disease. There is a beautiful drawing by my late colleague, Dr. Moxon, which he made to illustrate the same doctrine. Probably tubercular ulceration does not flourish in these cases because the chronic passive congestion favours fibrous degeneration—the cicatricial process to which we look to limit and starve the more dangerous and rapid disease.

It has been asserted that gout is prophylactic against phthisis and phthisis against gout, but this is probably a mistake. I have observed the conjunction more than once; that they do not often coincide is to be expected from their incidence on different periods of life. A similar criticism will apply to the presumed opposition between tubercular and malignant disease. Carcinoma affects elderly persons for the most part, while the majority of phthisical patients are young adults. Children with tubercle die before they can develop sarcoma, children with sarcoma die before they can develop tubercle, and adults affected with tubercle too often die before the age at which cancer is most frequent. In a patient of my own, aged fifty-eight, who died since my last lecture of cancer of the stomach, we found both old and recent tubercles in the lungs.

Jaundice.—With respect to the etiology of this common condition it is remarkable how little has been accomplished since morbid anatomy and animal chemistry began to be studied. It is little more than a century since the foundation of pathology as a science of facts, apart from speculation, was laid by Morgagni, and the knowledge of the chemistry of bile began with Berzelius; yet Boerhaave and Mead were not more ignorant than we of the cause of the most characteristic and remarkable form of jaundice. They, like us, could understand how when the duct of a gland is blocked by a calculus the secretion accumulates, distends the channels in which it runs, and is thus mechanically detained in the body. But we, like them, cannot explain jaundice without obstruction. Even in the case of obstructive jaundice much remains to be learnt as to the nature of cholæmia. If the bile, or any of its constituents, is so poisonous, why does it circulate for weeks and months without producing its effects? If it is innocent, why are those effects produced at last? In either case, why is a manufactured excretion reabsorbed when the factory is reduced to ruins and the exit unimpeded? and why, in this case alone, are the symptoms of cholæmia as constant and speedy as in other cases they are tardy and uncertain? But it is the cases of jaundice which—by an almost subjective use of the word—we call simple, that are so puzzling in their etiology. We surely cannot be satisfied by the current explanations—which refer icterus simplex to obstruction by inspissated mucus, which no one ever saw; or by swelling of the duct or of the duodenum, of which there is no proof; or by the pressure of impacted scybala, of which the presence is entirely hypothetical. Do we find anything analogous in the case of the kidney, the pancreas, the mamma, the parotid, or the lacrymal gland? In many cases of jaundice is there the slightest evidence of duodenal catarrh or of preceding obstipation? On the other hand, do we not frequently see evidence at the bedside, and proof after death, of considerable catarrh of the duodenal mucous membrane, and sometimes of fæcal accumulation in the transverse colon, and yet never jaundice? I might also adduce the youth and health which usually mark the patient, and ask why the supposed cause of obstruction should, after a limited duration, disappear as mysteriously as it came. Nor do we gain any help in explaining the cause of simple jaundice from Frerich's hypothesis of virtual obstruction, owing to blood pressure being extremely low. In the first place, there is not the slightest evidence that in these cases blood pressure is lower than usual; in the second place, we know that the pressure in the duct of a gland is often higher than that in the bloodvessels which supply it without secretion being suspended or reabsorption taking place; and, lastly, when we do know that the blood pressure is abnormally low, as in prolonged syncope, in anæmia, and in distension of the right side of the heart from pulmonary obstruction, we do not meet with jaundice.

Digitized by Google

The only case in which it does coincide with low pressure in the portal vein and high pressure in the hepatic is that of long continued organic disease of the heart, when we find evidence of mechanical pressure on the biliary ducts.

Surely it is better, instead of accepting vague hypotheses, which it is impossible either to prove or disprove, to regard jaundice, in the absence of demonstrable obstruction, as due to some other and as yet unknown condition. We shall thus at least regard each case we meet with in daily practice as a problem to be solved, not as an example of a well-understood physiological process. The fact is that, in spite of the great advances in our knowledge of secretion, among which are pre-eminent those due to our distinguished Bailey medalist, Professor Heidenhain of Breslau, much still remains to be done. The physical and chemical process, which ten or fifteen years ago seemed so beautifully clear—the blood, the basement membrane, and the secreting protoplasm, regulated by its vaso-motor and secretory nerves—though a true, is now found to be an inadequate, physiological conception. The unexpected results of partial removal of the kidneys and of complete removal of the pancreas in animals more closely allied to man than frogs or rabbits offer new problems—we may almost say new paradoxes—in physiology, which seem as hard and, so to speak, illogical as any that we meet with in disease.

This much, however, seems to be clear, that certainly most, and probably all, glands do much more work than secretion. When Bernard proved the glycogenic function of the liver, he showed that besides secreting bile it has a most important share in the metabolism of the body. Since then we have learned that the formation of urea has part of its process seated in the same great organ, so that it is probably as important in the transformation of proteids as of carbohydrates. And now two other functions, those of the accumulation of fats and of the formation of blood corpuscles, are more than probably associated with the liver. One used to explain these facts by the liver being in structure and vascular supply different from other secreting glands; but the effect of removal of the pancreas in producing glycosuria (as ascertained by von Mering) and the effect of removing the greater part of the kidney in producing polyuria with increased formation and excretion of urea (discovered by Dr. Bradford) shows us that glands constructed apparently on a purely secreting type have other functions—metabolic, destructive, or inhibitory,—the loss of which profoundly affect the vital processes of distant parts of the body.

But, in truth, this is only what we ought long ago to have learned from the familiar case of the testis. Castration is the most ancient of physiological experiments, performed in countless numbers, and even in this day of rebuke and blasphemy carried out without licence, certificate, or any legal restriction, and without anæsthetics, so long as the object is only the gratification of the palate or the convenience of life. Though forbidden for the trivial and unworthy objects of enlarging human knowledge and ultimately relieving human suffering, we are not forbidden from learning what experiments performed for other purposes teach us. The production of fat in the ox and the capon, the altered shape of the gelding, and the modifications of the teeth and horns and antlers in boars, and rams, and harts, prove how much the testis does beside secretion.

Lardaceous disease.—Our experience in this country seems to prove that the causes of this remarkable degeneration are far fewer and more definite than is commonly believed by German pathologists. It is certainly not produced by cachexia in general, nor by that of malaria or cancer in particular. Nor, we may say, from its absence in the great majority of such common diseases as syphilis and phthisis, is it directly the result of the ill health produced by either of these diseases. It belongs only to the latter stages of syphilis and to the most chronic forms of phthisis. It is only associated with disease of the bones, or with cancer, when they are attended with protracted suppuration; and it is found in cases of empyema and of accidental suppurative diseases, which have no so-called constitutional origin. The following table of [illegible] was drawn up by [illegible] they give the result of the post-mortem examinations held during a consecutive period of twenty-five years.

Cases of Lardaceous Disease at Guy's Hospital.

1855–75.			1876–1889.		Totals.
Prolonged suppuration	87	}	Prolonged suppuration	134	= 226
Some suppuration	5				
Phthisis	67	{	Phthisis	121	= 130
			Tuberculosis	9	
Syphilis	76	}	Syphilis	43	= 122
Probably syphilis	3				
No probable cause	6		No probable cause	13	= 19
	244			320	= 567

Syphilis, phthisis, and caries of bones are the three most frequent antecedents; but in nearly every case long-continued suppuration was present, while there were many cases of suppuration without phthisis, syphilis, or caries. The conclusion seems inevitable that the cause of the disease is, as Dr. Dickinson long ago maintained, continued loss of pus. Nevertheless, as that eminent physician once wittily remarked, nature is in the habit of letting us discover a major and a minor premiss, and then denying the conclusion. In these tables occur a few cases of general tuberculosis which may, but also may not, have been preceded by local caseous suppuration; and there are several cases of syphilis without record or anatomical evidence of prolonged ulceration or caries. Moreover, there are occasionally cases of prolonged suppuration in which no lardaceous disease results; as one, I may mention that of an elderly lady who had been for seventeen years the subject of empyema, with an external opening which daily discharged pus. In her last illness, when she died from bronchitis at the age of sixty-six, I found the liver and spleen unenlarged and the urine perfectly normal. Unless we argue not as pathologists but like a special pleader or like one maintaining a thesis, we must not try to get rid of the troublesome exceptions to any rule that we may discover.

The case is, after all, what we are well accustomed to in pathology and in natural history in general. No symptoms are pathognomonic, no *presagia mortis* are infallible. The great saying of Bishop Butler that probability is the guide of life, applies with striking truth to pathological and to remedial processes. In medicine, "always" and "never" must not be taken in their literal sense. If a statement is true of nine cases out of ten, it is practically valuable and theoretically important. The remaining exceptions must not be denied or explained away. We must not assume, because most cases are due to an ascertained cause, that all similar cases are due to the same. But on the other hand, the fact of exceptions must not lead us to neglect the remaining nine-tenths. Even in the exact and comparatively simple science of chemistry, the most refined and laborious experiments, repeated again and again by eminent observers in France, in Germany, in America, and in England, fail to confirm the truth of the familiar formula H_2O; although the results come so near the theoretical value that most men cannot help believing that the discrepancy is an accident. Nevertheless, the third place of decimals is intractable.

Gout.—The general etiology of gout has been settled by the consensus of popular and professional opinion from the times of Lucian to the present day, and we may assume that the intemperate use of liquor by the sufferer or his parents is the most important cause of this disease. But there still remain questions under what circumstances drink is most likely to produce gout, and what other conditions may develop it apart from drink.

In speaking of gout, I mean recurrent attacks of inflammation accompanied by the deposit of urate of soda in the articular cartilages. That there is a gouty diathesis, or rather, to use Latin instead of Greek, a disposition to gout, I admit. A man whose father and whose mother's father had this disease is more likely to have it than another; a man who has suffered from gouty arthritis three times is predisposed to a second attack. But this is not [illegible] of a child to tubercle, of one whose father died of phthisis to scrofula, or of those who [illegible] what we mean by this old word [illegible]

misleading associations, should be transferred to the chapter of antiquities which deals with the Galenical humours, the temperaments and dyscrasia of the blood. The disposition to a disease is either carried out or it is not. If the former, we have to deal with the fact of the disease; if the latter, we can never tell that the disposition exists.

The hereditary transmission of gout is undoubted. It is far more frequent than that of cancer, and perhaps than that of phthisis; but there are many cases of gout which are not hereditary. How are these acquired? Not all drink will produce it, for it is rare in Scotland; not all wines will produce it, for it is rare in Spain and Italy; not all malt liquors will produce it, for it is rare in Vienna and in Munich. Difficult as it is to explain the fact, this strange disease appears undoubtedly to belong to the most civilised, possibly over-civilised, times and nations, to the stronger sex, to the most vigorous period of life, to conquering races, to the higher classes of society, and to the most able of the community. The truth of the reflection with which Sydenham comforts himself under the pangs of this disease has been confirmed by every succeeding generation:—"At vero (quod mihi aliisque, licet tam fortunæ quam ingenii dotibus mediocriter instructis, hoc morbo laborantibus, solatio esse possit) ita viverunt atque ita tandem mortem obierunt magni reges, dynastæ, exercituum classiumque duces, philosophi, aliique his similes haud pauci."—*Tractatus de Podagra*, §15. No doubt the disease is far from being the exclusive appanage of rank and wealth. We see abundance of gout among our out-patients in London. But in them also it is hereditary, in them also it follows indulgence in strong drink, in them also it seems to choose the most vigorous and energetic for its victims.

Apart from hereditary disposition and from intemperance, there is no doubt we must recognise saturnine gout. It appears to be rare in the north of England,[4] and in the cases that have come under my own notice it has generally, if not always, been associated with beer-drinking and albuminuria. The relation of a fit of the gout to mental excitement or violent emotion seems too well attested for doubt; but there is no evidence that the disease was ever thus produced, and the fact may be plausibly ascribed to inhibitory action upon the excretion of nitrogenous products. Such nervous excitation would then take its place with an attack of indigestion as the exciting or determining cause of arthritis. In the same light we must regard mechanical injuries which will often determine gouty inflammation in a certain joint. In fact, it seems probable that the special liability of the ball of the foot and the root of the index finger to gouty inflammation depends upon their exposure to sprains and other injuries.

Rheumatism.—This term (*rheum*, *ῥεῦμα* from *ῥέω*) like gout (*gutta*) is historically associated with the exploded humoral system of medicine. No one now supposes that the latter depends on a drop of peccant humour distilling into a joint, or the former on a cold, moist catarrh flowing into the limbs and muscles; but just as the epithet "gouty" is by many applied with an arbitrary licence to bronchitis and dyspepsia, psoriasis, and iritis, so rheumatism is a convenient phrase for every ill-understood pain. In Germany the term "rheumatic" is commonly applied to every kind of disease which is believed, on more or less arbitrary grounds, to depend on the influence of cold. It appears to me that the word "rheumatic" should be used only as the adjective of the disease known as rheumatism or rheumatic fever, multiple synovitis with a definite clinical course, complications, and sequelæ. If it can be shown that an attack of tonsillitis, myalgia, urticaria, pleurisy, or pericarditis is related to rheumatic fever, we mark a real and valuable etiological point by calling them rheumatic. In the absence of such proof the use of the epithet is, I venture to think, of no value to our patients and mischievous to our pathological conscience.

The etiology of rheumatism as thus defined is still very obscure. The general belief that it follows exposure is certainly supported by striking cases. I do not remember, however, to have ever met with rheumatic fever following exposure to dry, cold, east winds, or to low temperature, as in a railway journey in winter. The most striking cases are those of men and women who get wet through and are unable to change their clothes. That some such relation to the weather exists seems shown by the geographical distribution of the disease, which is only too common in Northern Europe and the Eastern States of America, but is rare in the Mediterranean and the tropics, in Canada, Australia,[5] and the high, dry, and cold districts of America.

I endeavoured several years ago to ascertain whether the incidence of rheumatic cases in different periods of the year coincided with prevalent cold or wet, but the results are not easy of interpretation, and differ from those obtained by Dr. Gabbett[6] at the London Hospital and by M. Besnier[7] at Paris. Dr. Archibald Garrod, in his excellent monograph on rheumatism, comes to the same negative conclusion. Supposing that the connexion referred to is a real one, there are many reasons which may prevent its detection.

The following cases of rheumatic fever were admitted into Guy's Hospital during a period of ten years:—In September, 158 cases; in November, 136; in January, April, and October, 125, 126, 127; in June, August, and May, 111, 112, 108; in December, 102; in February and July, 99, 100.

Rheumatism is pre-eminently recurrent, and a slight exciting cause may bring on an attack in one who has before suffered from the malady. From an etiological point of view, we ought, therefore, to collect only first cases, but that would much limit our numbers. Again, the history of hospital patients is proverbially untrustworthy, and the chill to which they ascribe their rheumatism may have happened a week or more before the attack. Moreover, our climate is so uncertain that a man who is much subject to skyey influences, particularly if inadequately clothed, may be as effectually chilled with rain in July as in January. Even in hot weather people are apt to catch cold by throwing off woollen clothing and placing themselves in currents of cool air. During a wet month we often have few cases of rheumatic fever in our wards, and they are certainly often absent in the coldest time of winter.

The early age of the patients, its occurrence as a sequel of scarlet fever, and its undoubtedly hereditary character, are etiological facts which at present we cannot connect with one another, and time forbids dwelling upon them. But I must express my disbelief, or at least unbelief, in the chemical theory of rheumatism, which ascribes it to the presence of lactic acid in the blood. This conjecture, originally thrown out by Prout, was reasonable enough as the vague guess of a chemical pathologist; but since every endeavour to prove the hypothesis has rested upon chemical or logical fallacies, it is a pity that it still cumbers the ground. Moreover, we must remember that our exploded theories are not forgotten and do mischief to our patients. Probably most of us have been asked, as I have, whether lemons are not bad for lumbago, because rheumatism depends upon an acid in the blood.

The etiology of one of the diseases of the joints which used to be confounded under the title of rheumatism is now completely cleared up. I refer to gonorrhœal synovitis, a disease which we now know to be always and exclusively the result of urethral blennorrhagia, and to be totally distinct from gouty, rheumatic, syphilitic, or pyæmic arthritis.

A fourth kind of multiple articular disease, which Sydenham and Heberden described as "chronical rheumatism," and the great Irish surgeons Adams and R. W. Smith by the unfortunate title of "rheumatic gout," is obviously and widely distinguished from gout by the absence of deposits of urate of soda, and from true rheumatism by the age of the patients it affects, by its course and symptoms, and by the entire absence of inflammation of the heart. That osteo-arthritis, as it is called in our college nomenclature, regarded as an anatomical condition, may be the occasional result of rheumatic or gouty or gonorrhœal synovitis must be admitted; but that it has, in the great majority of cases, no such origin, but is, on the contrary, a separate clinical and pathological disease, is also beyond dispute.

My colleague, Mr. Lane, has with much ingenuity referred many of the distortions of the joints in this disease to traumatic causes. This explanation best applies to the cases in which one joint alone or one limb is the seat of the well known anatomical changes in question. Where a

[4] See Dr. Thomas Oliver's Goulstonian Lectures, 1891.

[5] So I am informed in Victoria and South Australia, but Dr. Church tells me that in the interior of New South Wales rheumatic fever is far from uncommon.

[6] Dr. Gabbett found the largest number of cases in November, October, and December, and the smallest in February, March, April, and May.

[7] M. Besnier found the largest number of cases in July, the next in June, April, and May, and the fewest in February, March, and September. The details are given by Dr. A. E. Garrod.

Digitized by Google

similar morbid state of the joints is more general it has, I think, always been recognised that it is, in part, the result of slight and individually insignificant, but numerous and long-continued, injuries; in other words, that it is the result of wear and tear. It has all the characters of chronic inflammation—i.e., it is free from the four classical signs or pyrexia, and it leads to hypertrophy with new formation of connective tissues. From this point of view, the disease is found, as we should expect, in the later periods of life, and in those who have been hardest worked. In fact, this arthritis deformans may, in its etiology, be compared to arteritis deformans, or atheroma of the aorta and great vessels. The same condition of chronic deforming and hypertrophic arthritis is very common in the lower animals. Writing on the subject in 1887, I referred to a large series of specimens from horses showing the disease in very marked form, and these were in the joints of the feet, on which the stress of a horse's work falls.

But while fully admitting the importance of direct and obvious injury as an occasional, and of long-continued work and strain as a frequent, cause of osteo-arthritis, there is no doubt that the same anatomical condition often occurs when no such explanation is possible: and when, moreover, there has been no preceding attack of arthritis, whether gouty, rheumatic, gonorrhœal, or traumatic. Such cases may occur in comparatively early life, long before degenerative changes have begun; they are more common in women than in men, and they affect the smaller joints of the hand before those most exposed to injury and pressure. Moreover, the clinical feature of the disease, its course, and especially its progressive aggravation, after the unfortunate patient is no longer able to perform even the ordinary movements of the limbs, prove that in its most characteristic form it is not secondary to any other disease, and not the direct result of mechanical or chemical causes. It is certainly etiologically connected with climatic conditions, for it is most common in those most exposed to our English climate, and is probably more often met with in Ireland than in any other country. I have seen striking instances of its being averted, or checked, or cured by removal to the south of France or to the east coast of England—the one warm the other cold, but both comparatively dry. Whatever the immediate and determining cause of this remarkable disorder may prove to be, it is, I think, certain that the term "rheumatic gout" is misleading, and the hypothesis of hybrid origin which it favours is opposed to all experience and scientific medicine, fatal to advance in pathology, and practically mischievous, as leading to slovenly diagnosis and inefficient treatment. The task of diagnosis is difficult enough as it is. If diseases were of hybrid origin and mingled pathology, it would be impossible.

Traumatic and idiopathic dermatitis.—We come now to the last group of diseases with the etiology of which I propose to deal—those which affect the skin. Here all the ghosts of dead systems of medicine, all the idols of the forum and the cave, all the baseless hypotheses and unproved conjectures that have met us in other parts of pathology, are crowded together. Remote from the progress of physiology and pathology, dermatology was long obscured by an antiquated and barbarous nomenclature, by pedantic distinctions between trivial differences, with confusion between broadly differing pathological states, while the treatment was complicated, empirical, and ineffectual. Our eminent countryman Willan was an accomplished physician, and viewed disorders of the skin from a point of view of the best general pathology and practice of his time; accordingly, his work, though scanty and imperfect, is, with few exceptions, accurate as far as it goes. Hebra's great treatise was constructed on the principles of general pathology laid down by the pioneer in morbid anatomy, Rokitansky; indeed, the chief fault of Hebra's work is that he follows too closely, and almost slavishly, the footsteps of his master. Since then the application of the microscope to morbid pathology and the discovery of the true part played by parasitic fungi and invading bacteria have cleared up many obscure problems, and the observations recently made in this department in France, in England, and in America [illegible] a worthy continuation of those begun by Hebra. Still, however, we find traces of the old vices of [illegible]

guineous temperament"; "scrofula" where there is no tubercle, "gouty tendency" where there is no gout, and "syphilitic taint" where there is no evidence of the presence of lues. Species and subspecies are still too many, and new diseases are too readily admitted; while even yet the principle which obtains in all other departments of medicine is not generally followed, that the name we give a disease should express its diagnosis and connote our best knowledge of its origin. To call a disease eczema without excluding scabies or fictitious origin, or to apply eczema to a slight degree of traumatic dermatitis, or to diagnose psoriasis or lupus without excluding syphilis is [illegible] words and deceiving ourselves.

As in other departments of medicine, an etiological arrangement of diseases is the best possible, since it points to prevention as well as to cure. Unfortunately our knowledge of causes is here, as elsewhere, very imperfect, and even when a cause has been clearly ascertained, we find it is liable to such modification as to lose much of its importance. Of these more or less completely ascertained causes the most obvious is local, mechanical, thermal, or chemical irritation. The skin inflames when rubbed, when chafed by rough clothing, when exposed to hot sun, or a cold wind, or to salt water, to the presence of parasitic animals or plants, or to chemical irritants like cantharides. This reaction, which we may call "common dermatitis," corresponds to the effects of cold air, dust, or other irritation in the conjunctiva, and the fauces, and the bronchi, and to inflammation of the stomach by locally irritant poisons. The result scarcely differs, whatever the nature of the irritant; cantharides cause serous bullæ, and tartar emetic ointment a pustular eruption; but with these, and a few other exceptions, the result produced depends on the strength and duration of the irritant much more than on its quality. It varies, however, with the vulnerability of the individual, and this, again, diminishes under repeated irritation. This tolerance the skin acquires more easily than any other tissue, no doubt because it is more frequently exposed to irritants. The face and hands very soon become accustomed to heat and cold and wet. The habitually covered parts of the skin are less readily hardened; it is doubtful whether the fauces and the bronchial mucous membrane, different as is its susceptibility in different persons, can become inured to the irritation of cold, dry air, or of dust by frequency of exposure; and the internal organs seem to be nearly destitute of this power of adaptation. Thus continued irritation of the liver by alcohol does not bring tolerance, but gradual aggravation, and the joints never become accustomed to the presence of crystals of urate of soda.[8]

It was one of Hebra's merits that he showed how artificial eczema may be produced at will by applying irritants to the healthy skin, but I venture to think that an equally important fact was overlooked by him when he wrote of "artificial eczema" and of scabies as a kind of eczema—namely, that in the great majority of cases of eczema no local irritation can be found, the skin reacts as if it had been irritated, but the proof of irritation is absent. It is these cases of idiopathic eczema which, surely, must be taken as the type of the disease, and they gain little light in etiology or in treatment from observation of traumatic cases. The best way to put the facts seems to be to describe the results of direct irritation as common superficial dermatitis of traumatic origin, and to define eczema as an idiopathic common superficial dermatitis with a special local distribution, course, and natural history which distinguish it as a separate disease. Nevertheless, it is important to bear in mind the anatomical resemblance between the purely secondary and the purely idiopathic cases, to recognise that the latter have not unfrequently their origin in the former, and that there are innumerable gradations of responsibility to be adjusted between the irritabile and the irritans.

Parasitic and contagious dermatitis.—Pustular [illegible]

[8] There are, however, exceptions which show that even the internal organs, and particularly the nervous system, may, under [illegible] conditions as a result of habit, cease to react to [illegible] markedly than the skin itself. The [illegible] cause vomiting or colic in a youth who [illegible] tiger. The stockdove's [illegible] often repeated, affect [illegible] [illegible]

titis (impetigo) of the scalp in children is often the immediate result of the irritation of pediculi and of the scratching to which their presence gives rise. Prurigo senilis is no less the result of the itching and scratching caused by pediculi upon an aged skin; and scabies is nothing but common superficial dermatitis, papular, vesicular, or pustular in degree, produced partly by the presence of the parasite and partly by the efforts of the patient to relieve the pruritus thus caused. But in the case of pustular scabies and impetigo of the scalp we must add a second etiological factor—namely, the contagiousness of the pus secreted, dependent upon the presence of more than one variety of microphyte. This explains the spread of the disease, as pus is conveyed by the patient's fingers to parts uninfested by the parasite. Another example of the contagion of pus is afforded by the multiplication of furunculi. There is little or no ground for the opinion that they depend upon "poverty of the blood" or any "constitutional" cause. The accidental inflammation of a deep hair-sac leads to a minute slough, with acute surrounding suppuration; and from this adjacent hair-sacs are infected, particularly when the surrounding skin is softened and a transfer of pus rendered easy by the use of warm and moist poultices. The efficacy of a disinfectant and astringent treatment confirms the same view.

To the above causes of dermatitis—local friction, heat and cold, wet and dryness, the irritation of scratching, the irritation of animal parasites, and the contagion of pus—we must add the presence of microscopic fungi, which invade the epithelium, the hairs and the hair-sacs, and produce ringworm, favus, and the other varieties of tinea.

Erythema and toxic dermatitis.—A second etiological group of dermatitis is due to poisons, not external, but conveyed by the blood and acting chemically, and I believe that here a common etiology is associated with common anatomical and clinical features, distribution, course, and treatment. Just as traumatic dermatitis is the type of the group to which eczema, impetigo, and scabies belong, so may we take as the type of erythematous eruptions that which is called forth by copaiba or belladonna. Under this group we may include the various forms of erythema combined under the name "multiforme" by Hebra, the roseola of authors, urticaria, and some of the cases which have been described as herpes, hydroa, acute pemphigus and dermatitis herpetiformis. They agree with eczema as being superficial dermatitis, not leaving scars, but they differ from it in several particulars. First, in anatomy the inflammation never forms permanent papules, nor small vesicles, nor pustules and crusts, nor weeping surfaces; while, on the contrary, it is almost always accompanied by subcutaneous œdema, frequently by wheals, and sometimes by hæmorrhage. Secondly, it is most certainly produced, not by mechanical or thermal, but by chemical, irritation, by the poison of a bee's sting, or a gnat's bite, or the sting of a nettle. It is never chronic in course, but fugacious. It produces smarting rather than itching. It is not nearly so symmetrical as eczema or psoriasis, and its favourite localities are different from those of any other kind of dermatitis, the forearm and back of the hand, the shin and instep, while it may spread diffusely over the trunk and face as an acute exanthem. We may compare the erythema urticaria produced by copaiba to that which follows the ingestion of mussels, crabs, and certain other articles of food. Still more frequently the eruption follows gastric irritation, when otherwise wholesome food becomes to an individual or on a particular occasion poisonous in its effects. One example of this *erythema ab ingestis* is afforded by the veinous congestion, œdema, and hypertrophy known as gutta rosea, wrongly associated with acne under the title "acne rosacea," which is not a primary obstruction and inflammation of the sebaceous glands, but the effect of frequently recurrent subacute erythema of the nose, cheeks, and chin. These flushings are, no doubt, frequently the result of excess in drink, but often of gastric irritation from other causes, or of ovarian disturbance, particularly about the climacteric period. Another etiological factor in the production of erythema is rheumatism. This is proved by the not infrequent appearance of erythema while the joints are still inflamed and the fever is high; also by erythema nodosum, so frequently occurring in those who have suffered from rheumatism; and, thirdly, by the hæmorrhagic eruption called "peliosis rheumatica," which bears all the characters of a true erythema. The last etiological point in relation to erythema, urticaria, and the rest of the group is their more frequent occurrence in children and young adults than in elderly persons, and among adults in women more than in men.

Dermatitis of nervous origin.—Another etiological group of cutaneous inflammations we have clear evidence of is due to disturbance of vaso-motor and trophic nerves. There are numerous and well-attested cases of bullæ and sloughing ulcers following injuries to one of the nerves supplying the upper or lower extremity. A large number are recorded in Dr. Weir Mitchell's well-known work, and many additional ones in Mr. Bowlby's Astley Cooper essay, afterwards published, with important additions, under the title "Injuries and Diseases of Nerves." There is now little, if any, doubt that the sloughing of the cornea which follows injury to the fifth nerve, and the acute sloughing bedsore which so speedily follows certain affections of the cord, are trophic lesions. But at present only one idiopathic disease can be brought under this etiological group—that, namely, which used to be called herpes zoster, and is now generally called zona. Here, however, I must pause.

In concluding this course of lectures I hope to have shown that etiology, when regarded as a part of the natural history of diseases, is not without interest or without important practical bearing. Much of what I have laid before you has been negative, and, I venture to hope, destructive criticism. But we must get rid of superstitious remnants, misleading analogies, loose definition, and illogical arguments before we can make progress in any branch of natural science. When the ground is cleared a solid structure may be built.

THE ETHICS OF OPIUM AND ALCOHOL.

BY F. J. MOUAT, M.D. EDIN., F.R.C.S. ENG.

I HAVE heretofore taken no part in the anti-opium controversy, for reasons which I need not detail; but when I perceive in THE LANCET in a notice on the subject that opium and alcohol are comparable, and stand on the same platform in their moral and material relations, I venture to think that this is not a correct view of the matter, and I hope to be able to show the grounds on which I dissent from that opinion, quite apart from the party and political purposes of the discussion, with which, in this article, I have no immediate concern. I have had an unusually varied experience of opium in its commercial, chemical, judicial, medico-legal, and therapeutical relations, from the accidents of the official positions which I occupied in India; and I deem it desirable to place that experience on record, to enable those who have not had the same opportunities to weigh the evidence I can produce, and thus assist them to judge more dispassionately the matter in relation to legislative action than is possible from the passionate appeals made on the subject. These I hold to be based upon erroneous information, however pure and sincere may be the motives which animated the originators of the movement. One of the most far-seeing and capable of the rulers of India, the late Lord Metcalfe, is reported to have said, when removing the fetters on the freedom of the Press, that if India is ever lost to Great Britain, it will be in the House of Commons. Let us hope that in any case it will not be upon the opium question. Reasons, correct and unanswerable, have been adduced by some of those best qualified to form an accurate judgment on the subject of the danger of tampering with native habits and customs, which are cherished with a tenacity unknown to those who have not witnessed them. I had many opportunities of ascertaining this in the conversations which I had with the Sepoy mutineers, who passed through the Alipore gaol on their way to the Andaman Islands. The lesson then learnt ought not to be so soon forgotten.

My personal and practical acquaintance with opium commenced in 1840, when I was appointed to officiate as assistant opium examiner to the Government, an office which I held for a year. During that time I had to analyse a sample of opium taken from each of the chests sold by auction in Calcutta for transmission to China, and this analysis was produced at the sale for the information and guidance of the opium merchants. The chief constituent which determined its commercial value and consequent price was the amount of morphia contained in each

Digitized by Google

sample. This information was sent to China with each consignment of the drug.

The subject was then new to me, and of so much interest that I wrote to an old fellow student practising as a medical missionary in Canton to know whether the chemical analysis was accepted in China as a correct estimate of commercial value; whether he had himself employed Indian opium in his practice; whether it was of greater or less efficacy than native opium; and if it differed from it, in what manner and to what extent? His answer was to the effect that so far as he could ascertain the Chinese paid little or no attention to our chemical reports, but judged it by a rule-of-thumb method of their own, based upon the smell, taste, and touch of the drug. He had no information as to its therapeutic action, as it was an expensive luxury beyond the reach of his patients, and was not used generally for medical purposes.

Shortly after this, in the following year, I succeeded Sir Wm. O'Shaughnessy as Professor of Chemistry and Materia Medica, and he made over to me the completion of the Bengal Dispensatory, which he was then compiling, and which was unfinished. I had therefore a far more minute and quantitative, as well as qualitative, analysis of the drug to make, and to institute a series of inquiries in the Medical College hospital regarding its therapeutic value, with a view if possible to ascertain to which of its constituent alkaloids it owed its anti-periodic virtues. These experiments were not concluded when he returned from furlough, and the work was restored to his hands; but as he was no longer connected with the College, and had no beds at his disposal, he did not continue the inquiry. He, however, completed and published the work. The net result of my inquiry, so far as it went, was that its properties as an intoxicant and anti-periodic were chiefly due to the morphia contained in it, but that it could not be substituted for quinine, which was at that time a very expensive curative agent.

I may mention here that Indian opium, carefully as the poppy was cultivated and the drug itself prepared, did not occupy the highest place in the scale, particularly as respected the most valuable of its constituents, morphia. The eminent French pharmacologist Guibourt assigned to it the fifth place, giving the highest positions to the opium of Turkey and Persia, which contained 14·78 per cent. of morphia, whilst Indian opium contained from 6·50 to 8 per cent. It is manifest, therefore, that if in India opium ceases to be produced as it is now, and is subjected to restrictions which are altogether inapplicable to that country, the finer varieties above mentioned will find their way to China (in these days of the daily increasing extension of commercial intercourse between all nations) as the luxury of the rich, thus being of doubtful advantage to the Chinese nation, and an injury to India, of which the magnitude and iniquity can scarcely be over-stated. This is not the place to discuss the physiological and therapeutic action of opium in the treatment of disease, but I believe it to be undoubted that it is a valuable febrifuge and pick-me-up in the fevers of all alluvial and marshy soils, and is procurable in the vast extent of thickly peopled districts, where no other remedy can be obtained. The older, and some of them are among the best, writers on tropical diseases placed great and well-founded reliance upon it. I have myself used it in my hospital practice in cases of pernicious remittent fevers, where there was an intolerance of quinine, and I had no reason to be disappointed with it.

I will now consider, as briefly as I can, its influence when used in moderation as a cause of disease and social disorder in the capital of British India. It is well known that alcoholic excess in Great Britain is responsible for a great part of the poverty and misery, of the crime and social disorders, and of the loss of reason which are national reproaches. In moderation alcohol is to a great extent comparatively harmless, and is in many cases valuable both as food and physic. But its indulgence in moderation is so difficult to secure as to have led for many years past to all kinds of repressive measures, but with very little effect, for the drink bill of Great Britain is still the greatest blot upon our escutcheon, and the most far-reaching instrument of evil against which we have to contend.

Some sixty years since a committee was appointed by the Government of Bengal to consider and report upon municipal improvements generally, and the provision of a fever hospital in particular, for the city of Calcutta. It was presided over by Sir John Grant, a senior puisne judge of the supreme court, and collected evidence for some years without arriving at any definite result, when, in 1843, I addressed the committee on the subject of the latter proposal, and suggested the building of such a hospital in the centre of the native town, to be attached to the Medical College, which was then under my administrative charge. This led to a considerable correspondence, which resulted in the building of such a hospital in 1848. In the course of the negotiations I was asked by the committee to afford them definite information as to the nature and extent of the accommodation required and the exact diseases treated in the then existing small and inadequate hospital and the out-door dispensary annexed to it. I complied with the request, and furnished tables of all the cases treated in both of the institutions mentioned for the years in which detailed records were kept, which were from the time of my appointment, when I introduced them, in 1841.

From that it appeared that in the male hospital there were admitted: In 1841, 1331 cases, with 179 deaths; in 1842 43 1230 cases, with 178 deaths; in 1843–44, 1676 cases, with 191 deaths; in 1844–45, 1297 cases, with 137 deaths. In the female hospital the admissions were: In 1842, 314 cases, with 27 deaths; in 1843–44, 389 cases, with 36 deaths; in 1844–45 380 cases, with 38 deaths. In both cases the beds were always occupied, so great was the need for accommodation. The average sickness in Calcutta, in a population then estimated at 300,000, was conjectured to be 18,000; but both figures were conjectural, as no census had then been taken. The out-door dispensary was of more importance. There were: In 1843, 12,330 cases; in 1844, 10,307 cases; in 1845, 14,552 cases; in 1846, 17,203 cases—in all, 56,392 cases. In the detailed tables furnished, all particulars connected with the diseases were contained. They included all classes of the native community, and a small proportion of Europeans and Eurasians. In the whole of this mass of sickness and mortality there was not a single case of either disease or death attributable to the use or abuse of opium, and yet there were not a few of habitual opium consumers in the city. There were a few—some eight or ten—cases of poisoning by opium, all of which were inquired into by the coroner, and none of them attributable to the ordinary employment of that intoxicant. The whole of the detailed particulars condensed into the figures above noted are contained in Appendix K to the third report of the Fever Hospital Committee, published in Calcutta in 1847, of which there is a copy in the library of the Statistical Society.

Next to disease in importance in dealing with substances which steal away men's brains, and depose sense and judgment from their seat to such an extent as to render them incapable of controlling their actions, is the commission of acts of disorder and crime. How stood Calcutta in this respect? I lived in the heart of the native city for thirteen years, during which time I was in constant communication with the magistrates and police superintendents, and most of the leading natives were personally known to me. On one side of me was a small, eminently industrious Chinese colony, all given to the habitual use of opium, and on the other side a very large aggregation of merchants and traders, of whom the up-country members were known to be given to opium. I traversed that city at least twice in every day in going to the European quarter, and never once saw an opium brawler, or heard of any one of them being in the custody of the police and in the courts for disorderly conduct under the influence of opium. What they did in their own quarters and dens, if the latter existed, for they were unknown to me, was confined to them, and never came under my personal observation. I am sorry to say that the worshippers of Bacchus were frequently in trouble, and were almost always European sailors from the shipping or soldiers from the fort. They were no worse than the same classes in those ports and garrisons in which they most do congregate. Many of them found their way to my hospital, generally brought in by the police, but the drunk, incapable, and disorderly were really few, the Calcutta gaol returns containing but 34 convictions in a single year, among 3921 inmates.

In 1868 I submitted to the Government of Bengal a special report containing the statistics of the whole of the prisons of the Province for the five years 1861 to 1865 inclusive. The prisoners sentenced were 302,374 in number, of whom all the particulars regarding caste, sects, classes, crimes, and sentences, as well as sickness and mortality, are contained

Digitized by Google

in the volume referred to. Among this large number there was a daily average of 5 per cent. of sick, and a total mortality of 6717. Of these not a single case of either sickness or death was returned as caused by the use or abuse of opium. The same remark applies to the crimes for which they were incarcerated. A more striking proof of the negative part played by opium in the causation of moral, social, or physical evils could scarcely be afforded. The figures were collected with the greatest care in monthly returns, and subjected to the closest scrutiny to secure their accuracy. It is true that Bengal is not strictly speaking an opium province, but there is nevertheless a sufficient number of consumers of the drug either for pleasure or as a remedy against fever to have made known their existence had they appeared in the courts of justice, been confined in the prisons, or treated in the hospitals. Even in the notoriously opium province of Assam I carried out an order for the suppression of opium in the gaols, when it was considered to have become a necessary of life in those accustomed to it from infancy. This was accomplished without any injury to them when the period of depression on first entering the prison was safely passed by the slight medical treatment required and strictly enjoined. A similar return for all the divisions of the Lower Provinces in relation to the castes and other particulars of the criminal classes, exhibited the same results, and is contained in my gaol report for 1867. The absence of a reference to opium was complete and absolute.

In addition to all the above particulars, the evidence afforded by the lunatic asylums was equally if not more striking. I was the official visitor of those institutions for several years, while at the head of the Prison Department, and it was my duty once in each year to visit, examine, and report on the state in which I found them, as well as to see every inmate and verify the records regarding them all. As I have no longer access to the records of these institutions I speak of them with some reserve, as I do not consider it right to rely upon memory alone in such important matters; but, so far as I can trust to my recollection, opium was conspicuously absent, whilst the victims of gunja or hemp were neither few nor far between. I am glad to perceive that an inquiry into this matter will be instituted in India, and I hope that it will include all the other conditions referred to above.

It may be said that the evidence adduced by me from official returns and personal observation is of a negative character. It is so for the very good reason known to the codes of jurisprudence, and embodied in the apothegm or legal maxim—"De non apparentibus et non existentibus, eadem est ratio." Can the same be said of the demon drink in relation to public morals and manners, to the gravest social evils, to crime and punishment, and to loss of reason? Could it be exorcised, the gain to the nation and to all mankind would be incalculable. The loss by the suppression of opium in India would be as incalculable in the other direction, and so far as that country is concerned, would amount to a national calamity. It is simply idle to suppose that the restriction of treating it merely as a medicinal agent would remove any of the unjust reproaches now heaped upon it, or be practicable in such a country as India. Even on the small stage occupied by it in this country the abuse of morphia has already attained lamentable dimensions, and cannot be suppressed in the summary manner, calmly advocated for the millions to whom it would apply, were any Government rash enough to adopt or attempt it, or possessed of sufficient means to carry it into effect.

CERTAIN QUESTIONS ON THE TREATMENT OF DIABETES.

BY CHAS. H. RALFE, M.D.CAMB., F.R.C.P.LOND.,
PHYSICIAN TO THE LONDON HOSPITAL, ETC.

(Concluded from page 904.)

ADMITTING, then, the risks attendant on a proteid diet, I would ask, are the relaxations proposed calculated to obviate them? I think not. They may satisfy a craving or help a jaded appetite, but, from a careful consideration of a very fair number of cases, I can confidently assert that the admission of any article containing starch or sugar is always followed by an increase of the disorder, which if persisted in becomes a definite advance. This intolerance of any partial resumption of saccharine material is more marked in some patients than in others, and some more quickly rally from an indiscretion, whilst some forms of sugar are better tolerated than others. Still, the fact remains that any article containing sugar ingested increases the glycosuria and diuresis, and further lowers the assimilative processes in the body. Neither a modicum of wheaten bread nor of mashed potatoes, or, what is a more reasonable suggestion, the use of subacid fruits, is sufficient to counteract the danger arising from the morbid products of a defective proteid metabolism, which is a danger incidental to the disease itself; whilst they are decidedly hurtful in other directions. To obviate this risk other measures are called for, which cannot be discussed fully now, and which are indicated by improving and maintaining the patient's strength by every hygienic and therapeutic means at our disposal. Two measures, however, I may briefly touch upon. The one is in the regulation of the amount of proteid food as the assimilative powers flag. There is very little doubt that diabetic patients are often encouraged to eat more animal food than they require or can assimilate; and I have seen the greatest improvement follow a reduction in the amount of meat, as also in a change from beef and mutton to fish, poultry, and such light food as tripe, calf's head, &c. A Paris physician of some eminence called attention to this point some years since, and stated that during the siege of Paris he noticed that his diabetic patients made considerable improvement, which he attributed to their having their flesh diet greatly curtailed. The importance of taking plenty of green vegetable food should be insisted on, to say nothing of watercress and other green salads. The second measure to improve assimilation and promote metabolism is massage, both general and over the abdominal viscera. When thoroughly carried out I have seen it effect a wonderful improvement in the patient's condition, in the restoration of appetite, improved digestion, relief of constipation, and a general increase of vigour.

With regard to the second question, I fear but little time is left for its full consideration on the present occasion, but as it is rather to elicit information than to impart any fresh facts, it will not take me long. It is strange, indeed, that, with a drug which is acknowledged as the only reliable therapeutic agent available for the treatment of the disease, no definite rules have been formulated with regard to its administration. Amongst the patients who come to me who have already been under treatment by their family attendant, I find a certain number who have already been ordered opium or one of its derivatives, others who have only been restricted as to diet. On looking over the reports of published cases I find the same uncertainty of opinion; some relying only on diet combined with some other form of treatment, others in which both diet and opium have been administered. There is therefore no unanimity of opinion as regards the time when treatment by the drug should be commenced. Some give it quite early; some wait till the disease is no longer removable by diet alone; whilst others postpone its administration till quite a late stage, or only employ it when complications such as boils, carbuncle, or gangrene occur. Some give it freely; others employ it sparingly.

With regard to the mode of administration, till Dr. Mitchell Bruce's instructive paper in the *Practitioner*, 1887, it was not demonstrated experimentally that subcutaneous injection of the drug was much less effective in restraining the glycosuria than when taken by the mouth. Even up to the present time it is not decided whether it is best to administer the drug when the stomach is empty, or during the process of digestion, when the portal circulation is in full activity. It is not conclusively determined whether opium in its crude form, or one of its derivatives, is best employed, or whether a combination is not most effective. Lastly, there is no consensus of opinion on the very important point how far we are justified in pushing the drug when the disease is prolonged, or when a fresh exacerbation occurs.

My answer to these inquiries must be brief; but I hope the conclusions I have drawn from observation of cases under my notice will be found to coincide with those of others, and will be strengthened by the experience of those present to-night.

1. With regard to the period when opium or its derivatives should be commenced, I have come to the conclusion that whilst the glycosuria can be completely removed by

Digitized by Google

diet the drug should not be administered, for this reason: that when it has once been administered, and then left off, on resuming it a much greater quantity is required to effect the same result than if even opiates had been continued throughout. This is in accordance with Dr. Mitchell Bruce's experience, for in one of his cases, quoted in the paper already alluded to in the *Practitioner*, in which the dose of morphia was reduced for a time, it was found that on again resuming the full dose it was necessary to increase it from four grains and three-quarters of morphia to seven grains before the same effect was induced. And here I would touch, parenthetically, on the danger of suddenly reducing the dose of this drug when it has been administered for some time, and especially in advanced cases. In two cases in which this has been attempted fatal results followed so shortly after that there could be no mistaking the cause. No hesitation, however, should be felt in commencing treatment by this drug as soon as the sugar fails entirely to disappear from the urine by mere restriction, as it is then that its power in maintaining the assimilative processes in the body is best exercised.

2. With regard to its mode of administration, the most decided results follow in diabetes when the drug is administered by the mouth, so that any other method need not be entertained. With respect, however, to the most effective period for administration, whether immediately before meals, so that it may quickly enter the portal circulation, or during digestion, when the assimilative processes are most active. I have found that administration about an hour after a meal has a greater effect in restraining diuresis than when taken on an empty stomach, that not much difference is effected on the sugar excretion, but that the dose taken shortly after food has one great advantage, especially when large doses of the drug are taken, of not disordering the stomach, or of causing nausea or impairing digestion as when taken fasting.

3. As to the best preparation of the drug. Solid opium, which was entirely relied on before the introduction of codeine by Dr. Pavy, has fallen into discredit, as I think undeservedly, and that alkaloid has almost entirely replaced it. But Dr. Mitchell Bruce has pointed out that morphine acts equally well as codeine as a sugar-restraining agent, and indeed is more active and more powerful, whilst quite as safe. Whilst endorsing all Dr. Mitchell Bruce says regarding the value of morphine in diabetes, and preferring it to codeine, on account of its greater uniformity of action, I have come to the conclusion that the full benefit of the drug in diabetes is not obtained unless some of its other derivatives are combined with the alkaloids. Though both codeine and morphine restrain the sugar excretion and the diuresis, still patients on whom the test has been made inform me that they experience a greater satisfaction when some preparation of crude opium has been added to either alkaloid. This can be done by combining liquor opii with acetate of morphia in solution, increasing or diminishing one or the other as circumstances seem to require; or else employing some of those extra pharmacopœial preparations which contain morphia as well as some other derivative of opium. Besides, I may say that diabetics often exhibit individual peculiarities as regards the different preparations of opium, which ought to be studied. In one case (a lady) codeine and morphine were tried on several occasions, and had to be given up on account of the headache and giddiness which were produced. Solid opium in the form of compound soap pill was, however, taken without any discomfort.

4. Lastly, in fixing the dose, at first it is important to find out the patient's own capacity for the drug, which varies greatly in different individuals, and discouragement should not be felt if the patient complains, or is in any way made uncomfortable on first commencing opium or its preparations. Each patient has his proper dose, and as soon as that is ascertained the full benefit of the drug will be felt. The real difficulty lies in determining the right time for increasing the dose, and when this becomes large to decide whether we should continue to increase it further. As a rule, we err, I think, on the side of too much caution, and often fail to obtain the full advantage of the effects of the drug by holding our hands when a certain effect has been produced. As soon, therefore, as the glycosuria ceases to be absolutely controlled by dietic restrictions, I venture to suggest that opium should not only be given in doses that sensibly affect the excretion of the sugar, but should be increased till either they entirely control the glycosuria, or no further reduction in the amount of sugar passed is obtained on increasing the dose. When this point is reached, we should recognise that the drug had been pushed to its fullest sugar-restraining capacity, and that the dose need not be increased till a further exacerbation of the disease takes place, always assigning as a limit to its increased use the point at which it ceased any longer to affect sugar excretion. How far and how long the use of opium or its derivatives may be carried without causing injury to the patient there is little means of saying. Diabetics are, as is well known, extremely tolerant of the drug, and it is impossible to judge of them, as regards the effects of opium, as is possible in the case of morphia *habitués*. Nor is it possible to ascertain what are the maximum doses that have been reached. Dr. Richardson, in a paper contributed to the Medical Society on the morphia habit,[1] mentions the case of a patient, a medical man suffering from diabetes, who for a period of eleven years took from one to three grains of morphia daily. Ultimately this patient died from what might be called premature old age. He was fairly happy up to a few weeks of his death, and Dr. Richardson had every reason to believe that his comparative easy life was considerably prolonged by the morphine. Dr. Mitchell Bruce, in the paper already alluded to, mentions seven grains of morphine as the maximum dose in one case, and six grains and a quarter in another, whilst under his care in the hospital. I have at the present time a patient who for two years has taken three grains and a half of morphine every day, having previously taken smaller doses. This patient has maintained his general health remarkably well; he is active, cheerful, and follows his occupation to his own and every one else's satisfaction, whilst the drug does not seem to have any of its usual effects—he is not drowsy or constipated; nor does he crave for the drug. For two years this dose has sufficed without any further increase being required; lately, however, the diuresis has increased, as well as the amount of sugar, and an augmentation of the dose must shortly be resorted to. The fact, however, that there has been this pause in the disease shows that opium, when given in effectual doses, does not need that these doses should be frequently added to. In this case, at the last increase, the dose of morphine was increased till no further impression was made on the glycosuria, which fell to about fifty grammes in the twenty-four hours, and has fluctuated between that and eighty grammes during the period mentioned. I have also given morphine to the amount of six grains in the day without observing any ill effects; but this quantity was only reached towards the end of the case, the longest period not being more than three months. So long, however, as opium or its derivatives affect a reduction in the excretion of sugar, I believe we may safely increase the dose; but as soon as the point is reached, and this frequently happens towards the close of the case, at which no further reduction is possible, and the sugar excretion rapidly gains ground in spite of dietetic restriction and the administration of opium, then I think it wise not to attempt any further increase.

I have thus, though I feel in a very incomplete manner, endeavoured to answer according to my own experience and observations the two questions which I proposed at the commencement of this paper for consideration, and trust they may be in accord with the general opinion of the profession.

Queen Anne-street, W.

[1] Transactions, vol. vii., 1885.

PARKES' TRIENNIAL PRIZE.—The prize of £100 and a gold medal for the best essay on "The Influence of Soil as a Factor in the Production of Disease, especially in Hot Climates; illustrated, as far as practicable, by Facts personally observed by the Writer," has just been awarded to Surgeon-Captain R. H. Firth, F.R.C.S., D.P.H., Medical Staff, now stationed at Dover. The assessors by whom the prize was adjudged were Dr. S. A. Monckton Copeman, M.A. Camb., of the Local Government Board; Dr. George Vivian Poore, F.R.C.P. &c., of University College; and Dr. J. Lane Notter, M.A., Professor of Hygiene at the Army Medical School, Netley. The essays sent in were five in number, and the assessors were unanimous in allotting the first place to the essay which was found to be the work of Surgeon-Captain Firth. The other essays will be returned to the writers on application to the secretary, Parkes' Memorial Fund, Royal Victoria Hospital, Netley.

ENLARGEMENT OF THE SPLEEN IN YOUNG CHILDREN.[1]

BY J. WALTER CARR, M.D., M.R.C.P.,
PHYSICIAN TO OUT-PATIENTS, VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

(*Concluded from page 909.*)

I COME now to the most important part of the subject—viz., the pathology of this enlargement of the spleen. Three diseases naturally suggest themselves as possible causes—ague, congenital syphilis, and rickets. We will discuss them in the above order. Ague is now so comparatively rare as an indigenous disease in London that one is apt to overlook it as a still possible cause of obscure conditions, and it is very necessary to bear in mind that although we may no longer meet with well-defined attacks of intermittent fever, yet malaria is much more insidious in its invasion in children than in adults, and may conceivably be the basis of the condition which has been described, especially as most of the patients came from the low-lying districts of Chelsea, Battersea, Fulham, and Putney, adjacent to the Thames. In vol. i. of THE LANCET of 1869, p. 325, is a statement by Dr. Andrew of St. Bartholomew's Hospital that almost every autumn he got some cases of ague which had originated in certain streets in Blackfriars. At a discussion at the Medical Society on Leucocythæmia, as lately as 1880,[2] Sir William Gull stated that there was malaria all over London; and in 1884 appeared a paper by Dr. W. R. Thomas of Sheffield,[3] describing cases of malaria, curable by quinine, amongst children in the low-lying districts of Sheffield, in which the spleen was generally more or less enlarged, sometimes enormously so. Moreover, malarial fever may be hereditary, at any rate from the mother. Henoch[4] mentions a case of splenic anæmia in which the mother stated that she had repeatedly suffered from intermittent fever during her pregnancy with the patient. In my cases the only hereditary histories obtainable were in Case 12, the father having had slight ague in Essex when a boy, and Case 15, in which the father had had ague twice, when in the army, before marriage; but probably during that period he had also contracted other diseases which had a more important bearing on the case. The connexion shown by Dr. Gowers to exist between leucocythæmia and ague is also suggestive of a possible connexion between the latter and splenic anæmia—a disease which, in many respects, seems to be allied to leucocythæmia. Such is the *a priori* reasoning in favour of ague being a possible cause of this splenic enlargement; but when we come to examine the cases individually we find but little evidence of such an origin. Of the children which were in the hospital, some of them for many weeks, or even months, not one had a temperature chart in the least degree suggestive of intermittent fever, only a pyrexia associated with pulmonary inflammation or the irregular febrile attacks similar to those occurring in the course of other profound anæmias; not one showed any improvement under quinine or arsenic. But more interesting and decisive is it to contrast the clinical history of the cases already described with that of an undoubted instance of ague with enlarged spleen in a child. A boy aged two years and a half was brought to me on June 19th, 1891. He had been born in Mooltan in the Punjaub. His father had been in India twenty years, and had had slight attacks of ague; his mother had had ague severely several times, both before and during her pregnancy with the patient. There was no suspicion of syphilis. When six months old the boy was seized with ague, and subsequently he had frequent and very definite attacks, with distinct cold, hot, and sweating stages. They had recurred since his arrival in England, a month before being brought to the hospital, and he had wasted considerably. When first seen the child was distinctly anæmic, fairly well developed, and not rickety; had slightly enlarged glands in the neck, axillæ, and groins; the liver was felt a full inch below the costal margin, the spleen projected two inches below it, reaching forwards to the nipple line and upwards to the seventh space in the mid-axillary line; the blood showed 70 per cent. of red discs, about one white to 100 red, and 60 per cent. of hæmoglobin. Here, then, was a case in which the physical signs and symptoms were absolutely identical with those of a moderately severe case of splenic anæmia—pallor and some wasting, the same condition of the blood, moderate enlargement of the spleen, and slight hypertrophy of the liver and lymphatic glands. The only difference was that in this case there was a definite history of repeated attacks of ague. Here, therefore, was a patient in whom the reaction to treatment might decide whether the resemblance was completed by a similar chronicity and unresponsiveness to drugs to that which characterises true splenic anæmia, and the test was a very fair one too, for the child must have been well under the malarial influence, not merely from exposure to infection after birth, but also by inheritance, in the most direct and powerful form, from the mother during intra-uterine life.

Here is the result: the child was given one grain of quinine three times a day; in a fortnight he seemed much better, and the spleen could only just be felt. In five weeks he had gained weight, and greatly improved in every way. The lymphatic glands were much as before, but neither the spleen nor the liver could be felt below the ribs; the red corpuscles had risen to 91 per cent., one white to 450 red; hæmoglobin 65 per cent. A more complete contrast to the progress of an ordinary case of splenic anæmia, a more convincing proof that the latter cannot, at any rate usually, be dependent upon malaria, could hardly be desired.

I turn now to the relationship to congenital syphilis, and here we have much stronger evidence of a definite connexion. In eight cases the infants were undoubtedly syphilitic, in six there was doubtful evidence, and in sixteen no evidence of specific disease; but even in several of the latter the possibility of syphilis could not, of course, in out-patient practice be by any means absolutely excluded. So far as can be ascertained, seven of the first fourteen cases died, and only three of the sixteen apparently free from specific taint. I think there is little doubt that the personal bias of the observer influences considerably, consciously or unconsciously, the percentage of cases in which, amongst a number of infants, hereditary syphilis will be diagnosed, some accepting as indisputable signs or evidence which others would either regard as worthless or would look upon with much doubt. Thus, if the observer start with a preconceived notion that these cases of splenic anæmia are essentially syphilitic, then he will probably find evidence, to him convincing, of syphilis in nearly every case, and will argue that as so many are proved to be syphilitic, any unexplained residue must be owing to insufficient knowledge of facts, which if known would probably confirm his view. If, like Parrot, we were to consider practically all rickets as due to specific taint, then, indeed, nearly every one of my cases would be syphilitic; so also, if cranial bossing or cranial tabes be regarded as sufficient proof in default of other signs, the percentage of cases of splenic anæmia due to syphilis would be at once increased; but this position has, I believe, been abandoned even by its original promoters, and my own clinical observations do not prompt me to make any attempt to rehabilitate the former faith. Necessarily, however, it must always be exceedingly difficult to say that a specific taint—insufficient it may be to lead to definite manifestations, but impossible to exclude absolutely—may not be at the bottom of an obscure disease like splenic anæmia. Apart, however, from all doubtful disputations, the fact remains that certainly a considerable percentage of these cases, and perhaps the worst among them, are associated with undoubted congenital syphilis; and the significance of the conjunction is not much diminished by the fact that in a large number of specific cases there is at no time any detectable enlargement of the spleen, although Cornil states that it is always hypertrophied. In the majority of hereditary syphilitic cases epiphysitis and interstitial keratitis are absent, yet no one doubts that they are essentially specific in origin. Often in examining syphilitic children I have found a slight splenic enlargement, the organ not feeling very hard, and there being no associated anæmia. This is doubtless comparable to the slight enlargement of the spleen described by Mr. Hutchinson in secondary syphilis, similar to that met with in the course of some acute specific diseases, and it usually soon disappears under treatment; but perhaps

Digitized by Google

at times the slight swelling may develop into a more pronounced hypertrophy, and eventually into a well-marked case of splenic anæmia. Probably all intermediate conditions obtain, and are illustrated among the thirty cases. Dr. Gee, in a paper read before the Medical and Chirurgical Society in 1867, stated that the spleen is enlarged by simple hypertrophy, so that it can be felt during life in about half the cases of congenital syphilis, and that in about one-quarter of the cases the enlargement is really great, and that sometimes the liver and lymphatic glands are hypertrophied as well; that the majority of cases of great enlargement die, but that sometimes the spleen gets gradually smaller; also that occasionally an enlarged spleen may be the only sign of an active syphilitic cachexia. In Wilks and Moxon's "Pathological Anatomy" it is stated that "in syphilis we often meet with hypertrophic enlargement of the spleen, no cirrhosis or lardaceous disease being present." But whilst fully realising the very remarkable connexion existing between congenital syphilis and enlarged spleen, we must admit that in a large number of cases, and many of them very severe, there is no evidence whatever of specific taint; cases too which run identically the same course and present the same pathological appearances as those associated with undoubted syphilis. But even more important is the result of treatment. The general rule in hereditary syphilis—at any rate as regards the earlier manifestations—is that the lesions either rapidly disappear under mercury, or else, if very severe and developed at an early period of life, soon progress to a fatal termination. But this is certainly not the case with hypertrophy of the spleen. The most active mercurial treatment, even in those cases in which the ordinary syphilitic manifestations are most pronounced, so far from being curative, appears to do harm rather than good, so far as the splenic condition and the anæmia are concerned. Of course it may be replied that anti-syphilitic remedies do not benefit locomotor ataxy due to syphilis, or quinine leucocythæmia started by ague; but these are very remote and indirect consequences of syphilis and ague respectively, whilst splenic enlargement, if due to syphilis, would surely have to be classed, from the period of its onset &c., amongst the conditions usually very amenable to treatment. We conclude, therefore, that though there must be a very close connexion between congenital syphilis and splenic anæmia, yet something further is required adequately to explain all the facts of the case, and that syphilis can be classed as a predisposing cause only.

Lastly, we have to consider the relation between rickets and splenic anæmia. In twenty-seven of my cases there was rickets, in four only slight, in the remainder more or less severe. At first sight these figures very strongly suggest that in rickets we have the true cause of splenic anæmia, and this was the view which Sir Wm. Jenner adopted in his classical lectures on rickets,[5] in which he says that "albuminoid infiltration of such a degree as to cause very great enlargement of the spleen is rarely seen except in those of the rickety diathesis." Before, however, we accept this seemingly tempting view, there are certain difficulties to consider: 1. That in the very great majority of rickety children no enlargement of the spleen can at any time be made out. I believe all observers have been and are agreed on this point. Although, as I have already said in regard to syphilis, absence of invariable association does not disprove a causal connexion, yet it at least suggests the probability of the action of some further cause, present only in a minority of rickety cases. 2. That there is no connexion at all between the severity of the rickets and the size of the spleen or the degree of anæmia. The splenic hypertrophy may be very great and the bone changes very slight, or *vice versâ*. Sir Wm. Jenner said that sometimes the bone disease is extreme and in others moderate or even trifling in degree. 3. In certain cases of splenic anæmia there is no evidence whatever of rickets. Case 7, in which rickets was absent, was first seen when the child was two years and a half old, and as she had only been suckled a short time, she might possibly have had a slight attack of rickets, all signs of which had disappeared; but the child (Case 17) which died at the age of only three months, with well-marked symptoms of splenic anæmia, had been fed exclusively at the breast; and Case 14 also, aged seven months, had had no food except the mother's milk. Of course it may be said that even in these cases, despite their early age and the absence of improper feeding, rickets would have been found if carefully looked for, and can, in fact, only be included by examination and section of the bones post mortem. It is interesting, however, that even Sir Wm. Jenner, after dwelling on the association of rickets with splenic hypertrophy, adds in a note: "I have now under my care a child, aged three months only, whose spleen reaches below the level of the umbilicus. The child is suffering from catarrh. There are no signs of rickets or tubercle." And so experienced and careful a pathologist as the late Dr. Fagge, in opening the important discussion on rickets at the Pathological Society in 1880, said that he had found a large fleshy spleen in many children who had been free from rickets.

But some supporters of the rachitic theory adopt a slightly different line of argument. Thus Dr. Dickinson, at the discussion just referred to, said that "where the visceral change is most marked, that in the skeleton is seldom extreme, as if the disease spent its force in one direction or the other"; or practically, in other words, that enlargement of the spleen alone may almost be considered sufficient evidence of rickets. It is, however, somewhat unfortunate, albeit perhaps rather suggestive, that *mutatis mutandis* the same thing has been said of syphilis. Thus Dr. Gee, as already quoted, says that sometimes an enlarged spleen is the only sign of an active syphilitic cachexia. Surely, however, this is begging the whole question; such a line of argument has the advantage of being necessarily unassailable directly; but it seems to me, whether applied to syphilis or to rickets, to be as incapable of proof as it is of disproof. Both the statements quoted may be true at times, particularly, I think, as regards syphilis, if some family histories are to be trusted; obviously both cannot always be true. Moreover, in some of my most extreme cases of splenic enlargement the rickety bone changes were very marked; in fact, as already stated, I can trace no definite relationship at all between the two conditions.

The foregoing remarks open up a question of wide interest as to how far we are justified in diagnosing rickets in the absence of distinct bone changes. I realise most fully that rickets is not a mere disease of the bones, but is a nutritional failure, affecting profoundly every one of the tissues and organs of the body; but, granting all this, may we not, ought we not to, admit that there may be conditions resulting from malnutrition in infants which are not necessarily rachitic—conditions which indicate a failure of nutrition along other lines than those producing the typical phenomena of rickets? In other words, are we not endeavouring to simplify our classification at the risk of collecting several distinct morbid conditions under one heading? True it is that under the rheumatic diathesis we have been able to bring together such apparently diverse conditions as arthritis, endo- and peri-carditis, chorea, pleurisy, tonsillitis, &c., to the great advantage of our pathology and treatment; but, on the other hand, how many totally different functional conditions have been accumulated under that convenient refuge word hysteria, with very many unfortunate consequences? That malnutrition may, and does, take on various forms is indicated by the fact that the most profoundly marasmic infants are seldom rickety. Should we not recognise more fully than perhaps we do at present that exposure to diverse unhygienic conditions—bad air, insufficient light, defects of diet, either as a whole or as regards one or more of the important constituents &c., acting in conjunction with different inherited tendencies or actual cachexiæ—may result in correspondingly diverse pathological conditions? In one case simple atrophy; in another ordinary rachitis with tendency to excessive fatness; in another rachitic bone change with more or less wasting; in another marked nervous weakness, shown by laryngismus, tetany, facial irritability, or by actual convulsions—conditions, without doubt, closely allied to rachitic bone change, but apparently bearing no very definite relationship to it, or finally, in some instances, leading to the condition with which we are now dealing—splenic anæmia. We know now that ordinary rickets is essentially due not only to improper feeding, but to a distinct kind of improper feeding. Is it not reasonable to suppose that other unhygienic conditions, acting alone or in combination, may have equally definite, though as yet not as clearly recognised, results? What the particular condition is which causes this splenic anæmia, whether it

[5] Published in 1880 in the Medical Times and Gazette.

Digitized by Google

be inherited or acquired, whether it be dietetic or aerial, I know not. That it is closely allied to the syphilitic cachexia, and even more nearly related to the causes which produce ordinary rickets (perhaps because rickets is more common than hereditary syphilis), there can, I think, be no doubt; very probably without some such predisposing element it will not develop. That neither of these diseases alone is the efficient cause I am almost equally certain. Dr. Cheadle, in a paper on rickets read before the British Medical Association in 1888, suggested that the cases of rickets in which enlargement of the liver and spleen is found are those modified by syphilis. No doubt as rickets predisposes to splenic anæmia, and as congenital syphilis does also, the combination of the two might be supposed to augment greatly this predisposition; but, on the other hand, if it be established that the disease can exist apart from rickets and also apart from syphilis, any theory which requires for its production the combination of the two can hardly be satisfactory.

The assumption of various well-recognised predisposing causes of splenic anæmia, requiring, however, some definite but at present unknown exciting cause for its development, would explain the fact that, whatever its apparent origin, the disease appears to run an independent course; that it presents, as seems now to be generally admitted, identical pathological appearances in children, whether syphilitic, rickety, even malarial, or showing no other cachexia; and that, finally, special treatment has but little influence over it; so that even in the most notably specific cases mercury seems useless, and that when associated with marked rickets the splenic hypertrophy and the anæmia improve much more slowly than the ordinary rachitic phenomena. If it be doubted whether any such single and definite cause as I have suggested be likely to be found, it may be remembered that until recently some dozen different causes of rickets were described, and it is only during the last few years, owing to the experiments of Mr. Bland Sutton at the Zoological Gardens and the writings of Dr. Cheadle, that the disease has been attributed more and more definitely to deficiency of certain essential elements, notably of fat, in the diet.

One more interesting question arises which has a bearing on the possible cause of splenic anæmia—viz., as to its age incidence. Up to now I have described it as a disease of very early childhood. In my thirty cases the oldest is two years and a half, and I have only been able to trace one case, No. 6, now aged three years and a half, in which the disease has persisted much beyond infancy; but does it ever occur in later life? In Fagge's Medicine it is stated to be "certainly rare." In the article on splenic anæmia in Keating's Encyclopædia it is said that the disease may occur in children of all ages, as well as in adults; but the only case referred to is one published in 1856 by Friedreich in a boy of five years and three-quarters. In the Pathological Anatomy by Wilks and Moxon (third edition, p. 495) the subject is thus mentioned:—"There are other cases in which the spleen is enlarged to a great size, and this enlargement is the chief, if not the only, disease that can be discovered. Thus Sir Spencer Wells removed a spleen weighing six pounds, this being the only disease discoverable in the body, and the blood not being leukæmic; and Mr. Squire met with a spleen weighing thirteen pounds, while the blood did not show a positive excess of white corpuscles. Similar cases have been met with of simple hypertrophy of the spleen without leukæmia, both in the living and in dead subjects. They are generally, but not always, at least during life, associated with anæmia, and so, indeed, as a rule, are all long-standing diseases of the spleen. These cases are the only ones that can be properly considered as pure examples of hypertrophy of the spleen; the cause of the enlargement is unknown, and the accompanying clinical phenoma need further investigation." I have met with one case in a boy of seven years, which might be considered an example of splenic anæmia. He was admitted from my out-patients to the Victoria Hospital for Children, Chelsea, on Feb. 6th, 1891. There was no evidence of congenital syphilis or of ague, and no history of acute specific disease since infancy. He had been ill three months, with increasing pallor and weakness. The boy was well nourished, but markedly anæmic; the liver reached two inches below the ribs and the spleen below the level of the umbilicus; it was hard, smooth, not tender. A systolic murmur, probably hæmic, was heard all over the cardiac area; urine acid, no albumen. Red corpuscles 42·6 per cent.; hæmoglobin 30 per cent.; no excess of white discs, but it was difficult to distinguish the red from the white, there being apparently intermediate granular corpuscles. The boy had attacks of pyrexia lasting several days, during which the spleen got larger, and diminished in the inter-pyrexial periods. There were no hæmorrhages. The anæmia increased, and on March 18th the red corpuscles were 33·6 per cent., one white to eighty-four red; hæmoglobin 20 per cent. Neither arsenic nor quinine seemed to have the slightest effect. On account of the hospital being closed the boy was sent to St. George's Hospital. His friends afterwards took him home, where he died, and unfortunately no necropsy was obtained. Except for there being no excess of white corpuscles this case presented all the characters of leucocythæmia. Can it, and can the other cases to which reference has been made, be considered true examples of the splenic anæmia which occurs in infants? Perhaps others may be able to mention similar cases occurring after infancy. At any rate, we may, I think, safely conclude that splenic anæmia is excessively rare after the first two or three years of life, that it occurs in fact during the period of incidence of rickets, and this would tend to increase the etiological relationship of the two diseases.

As regards treatment I have but little to add to what has already been said by implication. Mercury, even in the most obviously syphilitic cases, has seemed quite useless. In Case 1 it was given both internally and externally, and after four months there was no improvement as regards the spleen, though ordinary syphilitic manifestations had disappeared. Mercurial inunction was tried for some weeks in Case 6, in which the spleen still remains enlarged; and also in Case 15, which proved fatal. In Case 17, for a month before death, mercurial ointment was applied and grey powder given by the month. The only patient in whom the spleen seemed to get smaller under mercury was Case 14, and this was a mild case from the first. Neither quinine nor arsenic had any apparent effect; thus in Case 4, liquor arsenicalis was given for five weeks in increasing doses up to three minims three times a day, and was eventually left off, owing to vomiting, without having caused any improvement. Also, in Case 8, two minims of liquor arsenicalis were given every four hours for some time without result. I should add, however, that in Case 5, a very severe one, the child was taken out of the hospital by the parents, after being in only a few days, and Mr. Mordaunt Wheler of Battersea-park-road, under whose care she then came, tells me that he treated her with increasing doses of bromide of potassium and liquor arsenici hydrochloricus for over twelve months, until complete recovery ensued. One great difficulty, especially in out-patient practice, in giving any of these remedies a fair trial lies in the frequency with which the course of special treatment is interrupted by attacks of gastro-intestinal or respiratory catarrh—often protracted and severe,—to which these anæmic children are particularly prone. As a rule, the most efficient treatment, in addition to suitable food &c., appeared to be cod-liver oil and iron, and I am inclined to think that the latter especially may be pushed with advantage. Thus in Case 8, one of the most severe of the series, the red corpuscles increased in six weeks from 37 to 63 per cent., and the hæmoglobin from 25 to 38 per cent. under reduced iron, given up to eight grains a day. It should, however, be added that in this case the anæmia had previously to the former estimation been unduly increased by severe epistaxis. Again, in Case 22, tincture of perchloride of iron was given up to five minims three times a day for several weeks, and during this time the spleen got very considerably smaller and the child's colour and general nutrition greatly improved. Thus, in the future, whilst of course treating any obvious symptoms of syphilis, I shall be inclined to rely for the improvement of the splenic anæmia proper upon the, as far as possible continuous, administration of large and increasing doses of iron.

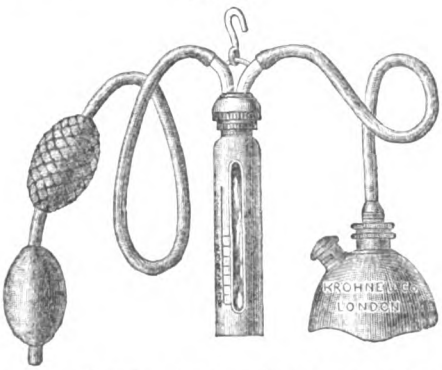
In this paper I have not brought forward new facts or advanced novel theories, but have simply endeavoured, by describing, and as far as possible following out, the history of thirty cases of varying degrees of severity, to arouse interest, to promote inquiry, and thus to increase our common knowledge of the origin, course, and so ultimately of the successful treatment of a disease of which at present we can only say that its pathology is obscure, its prognosis serious, and its treatment very unsatisfactory. I have to

Digitized by Google

thank my colleagues at the Victoria Hospital, Dr. Ridge-Jones, Dr. Colcott Fox, and Dr. Drewitt, for allowing me to make use of their cases in the wards, and the house physician, Mr. Gale, for valuable help in the examinations of the blood.

Bloomsbury-square, W.C.

A MODIFICATION IN JUNKER'S CHLOROFORM INHALER,



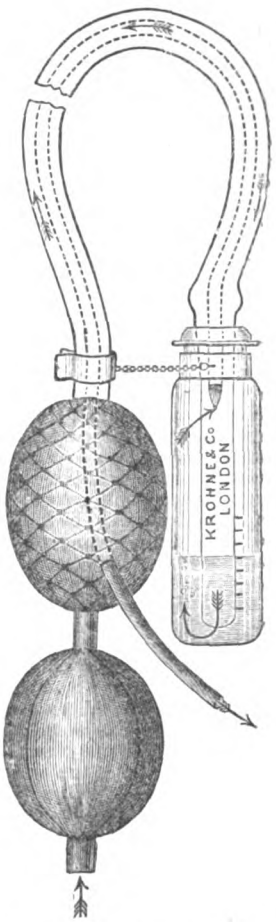
SPECIALLY DESIGNED TO PREVENT CERTAIN ACCIDENTS WHICH HAVE FROM TIME TO TIME OCCURRED WITH THE ORDINARY APPARATUS.

BY FREDERIC HEWITT, M.A., M.D. CANTAB.,

INSTRUCTOR IN ANÆSTHETICS AT THE LONDON HOSPITAL, ANÆSTHETIST TO CHARING-CROSS HOSPITAL AND TO THE DENTAL HOSPITAL OF LONDON.

JUNKER'S chloroform inhaler is now so widely used that there is no necessity to refer at any length to its merits or to describe it in detail. Many use this apparatus whenever chloroform has to be administered; some employ it only for maintaining anæsthesia during operations within the buccal or nasal cavities; there are others who consider the inhaler specially serviceable in obstetric practice, and only have recourse to it for allaying the pains of labour. But all will, I think, agree that Junker's apparatus is one of the most useful ever brought before the notice of the profession. I reproduce, for the benefit of those who are not fully acquainted with the ordinary inhaler, an engraving showing its main features.

FIG. 1.



The bottle, filled to about one-third with chloroform, is suspended by a little hook from a button or button-hole of the coat of the administrator. Air is pumped through the anæsthetic by means of a hand-bellows, an indiarubber tube, and a *long* metal tube passing to the bottom of the chloroform bottle. The last-named must be imagined, as it is not seen—or, rather, is only partly seen in the engraving. The air, laden with chloroform vapour, escapes from the bottle by a *short* metal tube at its upper part, connected with an indiarubber tube terminating in a face-piece. The indiarubber tube leading from the bellows to the bottle may be termed the afferent or bellows tube; that leading from the bottle to the face-piece may be termed the efferent or face-piece tube. When it is desired to keep up chloroform anæsthesia without employing a face-piece, as in certain mouth and nose operations, the face-piece is disconnected, and the efferent tube, usually terminating in a bent metal mount, is passed into the buccal or nasal cavity.

Now there are two accidents which have from time to time occurred with this apparatus: 1. By an oversight the flexible afferent and efferent tubes have been attached to the wrong metal tubes of the bottle—i.e., the afferent or bellows tube has been fixed to the *short* metal tube of the bottle, and the efferent or face-piece tube has been connected to the *long* one. The result has been that liquid chloroform has been pumped into the face-piece, and in some cases, when a mouth- or nose-tube has been used, into the mouth or nose of the patient. 2. Owing to the bottle containing the chloroform being simply attached by means of a hook to the coat of the administrator, it is liable, unless constant care be exercised, to become tilted, so that the liquid gains access to the exit or efferent tube leading to the face-piece. This latter accident is most likely to take place if the bottle is suspended in such a manner that it is liable to touch the pillow of the table or couch when the anæsthetist is leaning over his patient. Should the administrator be tall, there is, of course, less liability to this accident than under opposite conditions.

Although the above accidents are rare, it seemed to me that it was worth while to try to prevent the possibility of their occurrence by some slight modification in the construction of the inhaler. Whilst fully recognising the undesirability of modifying such an excellent apparatus as that under consideration, I nevertheless felt that I might be excused if the attempt had the effect of overcoming the liability to

FIG. 2.

the accidents to which I have alluded. That such accidents have taken place there is ample proof; and, unfortunately, fatalities have on more than one occasion resulted. This, I trust, will be a sufficient reason for my adding another "modification" to the already long list. It may be argued that everyone who gives an anæsthetic should see that the apparatus is in order, and should be careful in the use of it. This must, of course, be admitted. But we are all of us liable to mistakes; operations are often conducted under conditions which are not the most favourable for forethought and attention to detail; and an apparatus such as Junker's may be so unexpectedly required during an operation that the anæsthetist may overlook the fact that the tubes have been reversed.

The accompanying engraving (Fig. 2) shows the modification which I have ventured to make in Junker's inhaler. It is a very slight one, and in no way interferes with the ingenious principle of the apparatus. Air enters, as usual, at a valve in the bellows. The indiarubber afferent or bellows

Digitized by Google

tube is considerably wider than that ordinarily employed. The same may be said of the long metal tube in the bottle to which the bellows tube is attached. Air passes through these, as in the ordinary apparatus, to the bottom of the bottle, and, when the bellows is working, bubbles up through the chloroform, as shown in Fig. 2. The arrows indicate the direction of the air-currents. The air, now laden with vapour, returns from the bottle by very much the same route as that by which it entered, but through tubes contained within those already described. *The efferent tube travels back—in fact, through the afferent tube,* the space between the tubes serving for the afferent current. The efferent system commences at a small orifice in the upper part of the long metal tube of the bottle. To the inner aspect of this orifice in the wall of the long tube is soldered one end of a short metal tube of such calibre as to be readily contained within the larger tube. This small metal tube quickly joins the indiarubber efferent tube, and thus allows of a communication between the latter and the interior of the chloroform bottle. The rubber efferent tube passes on and on through the larger afferent tube (as shown by the dotted lines) till it emerges from the hand-bellows. Arrows indicate the efferent current. By this plan there is no possibility of the mistake above alluded to being made; the inlet and outlet tubes of the bottle cannot have the wrong indiarubber tubes connected to them.

The modified inhaler is very conveniently worked, as shown in Fig. 3. The wide afferent tube, which contains

FIG. 3.

the efferent tube, is passed round the neck. Attached to the upper part of the bottle there is a short chain, at the free end of which there is a clip for grasping the afferent tube. In this way a kind of collar is formed, and the whole apparatus is rendered much less mobile than usual. The bottle is so high up that there is no likelihood of its getting tilted by the pillow, even though the anæsthetist be of short stature. In addition to these points, I have found that there is a great convenience in being able to work the inhaler without the two long flexible tubes ordinarily supplied with it. When space is limited, and when there are several assistants, as in protracted and difficult jaw and mouth cases, the long tubes of the ordinary inhaler are liable to become entangled, or kinked, or to get in the way of the operator.

I may say, in conclusion, that I have used this apparatus for the last nine months, and find that it answers my expectations in every respect. Messrs. Krohne and Sesemann, of Duke-street, Manchester-square, are the makers.

George-street, Hanover-square, W.

THE TREATMENT OF THE PEDICLE IN OVARIOTOMY.

BY SKENE KEITH, M.B., F.R.C.S. ED.

WHEN we review the history of ovariotomy we find, in the treatment of the pedicle, a beautiful example of how our methods improve with increasing general knowledge; and how experience gained, perhaps in different branches of practice and of science, assists us in many ways. When we look back, with our increased knowledge and experience, and condemn some form of practice, we must not therefore judge and disparage those who adopted it; for although we now know that it is not desirable, yet at the time it may have been better than any other. It is easy to criticise the past by the knowledge of the present, and in doing so there is a proneness to forget that we also would, in all probability, have congratulated ourselves that we were doing the best for our patients had we followed a like practice. In the early days of ovariotomy it was evidently supposed that the distal end of the pedicle would, or might, slough, or that it would not be safe to leave a ligature in the abdominal cavity without having some means of exit kept open for its removal. The ligatures, therefore, were left long, and were brought outside at the lower angle of the wound. There was usually more or less suppuration, from which it was concluded probably that the distal portion of the pedicle became disintegrated. The ligatures loosened and came away easily, though at times their withdrawal was effected with much difficulty. Bearing in mind what was known of this subject thirty years ago, it was a great advance when, instead of allowing the pedicle to slough inside the abdominal cavity, as it was supposed to do, and sometimes undoubtedly did do, it was fixed by means of a clamp, so as to allow of its sloughing outside, and in a position of comparative safety. The results obtained by most surgeons with the clamp were not particularly brilliant, owing to want of knowledge and appliances. The results would have been not only successful, but brilliant, had it been recognised that septic formations about the clamp could have been prevented by the use of antiseptic dressings; or if formed, their access to the raw surface of the wound or passage into the peritoneal cavity averted. We have abundant evidence of this at the present day. Every now and again a woman, the subject of ovarian disease, presents herself for operation, who also suffers from prolapsus uteri. In those cases the womb must be fixed up by a clamp on the pedicle; and the patient recovers as easily and as well as when the pedicle is treated intra-peritoneally. A greater advance in every sense of the word was made when Baker Brown used the actual cautery. It must be remembered that no one at that time could explain why the short or long ligatures or the clamp seemed often to be responsible for the death of a patient. The value of rigid cleanliness—asepsis—was not thoroughly and generally understood, though it was evident that some surgeons did understand its value. It was not till Sir Joseph Lister insisted on the destruction of septic agents that there was any general and real advance in this direction; and it has since been found that they can be excluded or rendered harmless if everything be perfectly clean. Baker Brown did away with ligatures and with clamps; and by preventing bleeding from the pedicle by the hot iron, he eliminated one great source of danger and of death. The cautery gave unrivalled results, and its universal adoption in the treatment of the pedicle was, I believe, alone prevented by increase in our general knowledge, teaching us to have our ligatures in a condition of perfect cleanliness. The cautery has still advantages over the ligature, the chief one being that if there be bleeding it will occur at once, and not, as is the case with the ligature, some time after the abdomen has been closed. When the pedicle is specially broad the cautery does admirably. On the other hand, when thin and easily compressible, the ligature is as safe, and perhaps somewhat more easily applied. The method of use is simple; the pedicle is compressed by a clamp, and in spite of the numbers that have been made, that of Baker Brown remains the best. The blades are screwed together as tightly as possible, and a damp towel is placed below the clamp, to prevent burning of the skin. The cautery irons should be large, so as to give out great heat; and

Digitized by Google

they ought to be used as hot as possible, a white heat being better than a dull red one. At first sight the principle of this may appear to be wrong. It is, however, not so; because the cauterising action is chiefly gained through the blades of the clamp, which are to be made so hot that the finger can just touch them. The pedicle is to be burnt down flush with the clamp, and by the time this is done the clamp will usually be hot enough. The pedicle is grasped below the clamp by a pair of forceps, so that the stump may not slip into the abdomen suddenly when the clamp is removed. The removal is carefully managed, the compressed portion of the pedicle will, if all be satisfactory, have the appearance of a piece of horn, and the pedicle is then allowed to sink into the abdomen. With properly heated cauteries all this can be accomplished in three or four minutes. In cases of exceptionally broad and fleshy pedicles, in which it is not advisable to ligature in two parts only, the cautery is seen to most advantage. Bleeding never occurs after the abdomen has been closed, and to prevent it at the time of operation the two essential points are the screwing up tight and the heating of the blades of the clamp.

The common and, indeed, almost universal way of securing the pedicle is by means of a ligature. Of all the different materials of which ligatures can be made silk is the best and most convenient, although before the days of antiseptics Dr. Keith obtained excellent results by using fine iron wire. The ligature of silk ought to be just so thick as to withstand the strain the operator can put upon it; there is not any advantage in having it thicker. The silk must be chemically and not only apparently clean. This condition may be obtained in various ways. As simple and effective a way as any is to boil it and then keep in a 1 in 20 solution of carbolic acid. In this solution it may remain for many months without deteriorating in strength, and the quantity of carbolic acid which is introduced into the abdomen is so small that no possible harm can result. There are various ways of applying the ligatures; the pedicle must always be transfixed unless it is exceptionally thin. The method of tying commonly used is either the Staffordshire knot or tying each half separately, the loops being interlocked, and the whole afterwards included in a single ligature. A better plan is to transfix, and tie each half without interlocking the loops, so as not to run any risk of drawing on the knot of the first loop when the second is tied. The two double ends are tied together, and when this is done it is remarkable into what a small compass the pedicle is drawn. The single encircling ligature is dispensed with, and it is difficult to see of what advantage it can ever be. Mr. Syme knotted together the double ends in this way when tying piles.

For the treatment of the pedicle of ovarian tumours I have used the cautery 132 times, in fourteen both pedicles being secured from hæmorrhage in this way; and while my own experience in the use of the ligature is somewhat greater than with the cautery, I believe that as time goes on I shall tend to use the cautery more, employing the ligature only for slender pedicles, and also, of course, for cases requiring enucleation, in these latter it not being necessary to treat *en masse* large portions of tissue.

Charles-street, Berkeley-square, W.

THE INFLUENCE OF MENTAL DISTURBANCE IN PRODUCING ORGANIC DISEASE.

BY H. GRABHAM LYS, M.D. LOND.

(Concluded from p. 905.)

Digestion.—I pass on to the relation between digestion and mind. No function is more closely related to mind than digestion; disorder of either will worry its fellow; irritability of temper may be attributed to indigestion on pretty ordinary principles; there is more difficulty in assigning the principles on which indigestion follows mental disturbance; but there can be no question of the fact. Maybe it checks secretion of the gastric juice. Physiologists do not indeed question a nervous influence on secretion and nutrition apart from vaso-motor change, though the question of separate trophic nerves may still be an open one. Mr. Hutchinson, at a meeting of the London Hospital Medical Society in 1888, dwelt on the influence of emotion on some of the secretions, and more especially instanced cases of persistent dry mouth following some mental shock. In the opposite direction, the lacrymal secretion affords a striking example. In a case of gastric fistula in man, Beaumont directly observed the arrest of the gastric secretions by anger and other severe emotions. Probably also movements of the stomach may be inhibited by emotion; irritability or sluggishness of bowels doubtless is often referable to mental disturbance according to its kind; the latter disorder reaches its climax in the extreme constipation of melancholia.

Jaundice.—Dyspepsia, however, can hardly be termed an organic disease, and I do not propose that it definitely leads to any organic disease of stomach, but it leads me on naturally to the subject of jaundice. Now, it is doubtless familiar to many of us that simple jaundice often directly follows some mental emotion. I might quote the well-known instance of Sir Thomas Watson's, where an unmarried woman rapidly became yellow on its being disclosed that she had borne children. But, indeed, I think a short experience is sufficient to convince one on this point. Two cases impressed themselves on my memory during my house physiciancy: one was a youth who was intensely disappointed at being discharged from the service of the Post Office because he had not grown tall enough; and the other was that of a girl whose *fiancé* was killed in a railway accident. In each case the jaundice followed very shortly upon the mental shock, and in neither was there any reason to suspect catarrhal or epidemic influence. I take this opportunity of endorsing the protest against the generic term "catarrhal jaundice" on these grounds. The question, how is jaundice caused by mental disturbance, is one which, so far as I know, has received no explanation. I do not see how it can be referred to any vaso-motor disturbance; still less to any obstruction in the ducts or any alteration of the proportion of bile reabsorbed; one can only say that it must be due to some influence on the hepatic cells, which, while leaving them competent in some degree to complete the formation of bile pigment, interferes with the excretion of it. But I have not yet done with jaundice; if I had to leave it there, I should not be able to claim in it, as I do, a most interesting example of the passage of functional disorder into definite organic disease, and the inference which may be drawn from the nature of that organic disease as to the pathology of the minor disorder. It is perfectly well known, not only that acute yellow atrophy often follows immediately mental shock and runs its course rapidly, but also that it often supersedes simple jaundice of weeks' duration. In acute yellow atrophy there is a definite disorganisation of liver cells, and I need not, I think, say more as to the direction in which these facts point in the pathology of simple jaundice.

Diabetes.—Next, diabetes, both mellitus and insipidus, is acknowledged by all authors to follow as a direct result of mental anxiety or shock. Fagge quotes from Dr. Herman Weber the case of a gentleman who became diabetic on two separate occasions, at an interval of nine years, under the pressure of intense anxiety from impending commercial ruin, recovering on each occasion at a turn in his circumstances. I think that cases of diabetes mellitus are rare without some history of mental disturbance more or less striking immediately preceding the attack. Diabetes insipidus is a much rarer disease, but mental shock and emotion are mentioned among its causes. The pathology of both forms is readily referable to vaso-motor dilatation. I have already dwelt on vaso-motor changes from mental disturbance, and the only difficulty in this case is its apparent limitation. In diabetes insipidus there would appear to be vaso-motor dilatation only in the renal circulation, while in diabetes mellitus, in addition to the renal, the hepatic circulation, or, if we follow Pavy's views, the whole splanchnic area becomes dilated. There is no cause to assume, as in the case of jaundice, any nerve influence on the gland cells; it seems to receive a ready explanation in mere vaso-motor change.

Cirrhosis of kidneys.—Granular kidney has from time to time been attributed to mental anxiety. Dr. Clifford Allbutt, writing in the *British and Foreign Medico-Chirurgical Review* in 1877, while refraining from any explanation, asserted as an undoubted clinical fact that granular kidney was very often caused by prolonged mental anxiety; he suggested that the change might be such derangement of the nutrition of the kidney as occurs in the liver in diabetes; but it is difficult to see how such derangement could cause granular kidney. Dr. George Johnson, writing later, says that the explanation of this view is that mental anxiety is

Digitized by Google

a cause of dyspepsia, and functional albuminuria often depends upon the excretion of some abnormal products of imperfect digestion, and this has been mistaken for organic Bright's disease. The question whether granular kidney and arterio-capillary fibrosis may not be themselves primarily, like the cardiac hypertrophy and arteritis deformans, associated with them, the result of increased tension, is one which has, I believe, always hitherto been answered in the negative, but one which I think may still reasonably be entertained. Dr. Clifford Allbutt, to whose paper I have already referred, says that high tension cannot cause granular kidney, because it is so often absent in cases where the tension is high from cerebral disease. I doubt, however, whether, in this association, the cerebral disease is not always secondary to high tension, and whether, if the kidney were carefully examined, slight granular changes and thickening of its arteries, as of those of the brain, would not be found. We know from clinical experience that the degree of granular kidney cannot be measured by the degree of arterial degeneration, and therefore that there is some further cause for an advanced cirrhosis of the kidney beyond that which produces the general arterial degeneration; and that cause, doubtless, is the excretion through the kidney of the alcohol of over-drinking, or the deleterious excretives of over-eating.

Chorea.—Then, for the lack of an explanation, I must not pass over Chorea. Its pathology seems to me as inexplicable as that of any disease known. There can be no doubt that it is often due to fright; in many cases it follows such an event so immediately that it seems impossible to disregard it. Equally irresistible is the evidence which attributes it in some cases to imitation. How to reconcile these facts with its still more certain relations with rheumatism and endocarditis I must leave to others.

Cancer.—And now, lastly, what is the relation of malignant disease to emotional causes? I can only refer briefly to the conclusions which many who have had the largest experience of disease have arrived at. "Too often," says Sir James Paget, "cancer quickly follows deep anxiety, deferred hope, or disappointment." Dr. Murchison says: "I have been surprised at the frequency with which patients suffering from primary cancer of the liver have traced the commencement of their ill-health to protracted grief or anxiety. The cases have been far too numerous to be accounted for on the supposition that the mental distress and the cancer have been mere coincidences." Dr. Snow asserts, in THE LANCET of 1880, his conviction that the vast majority of cases of cancer, at all events of breast and uterus, are due to mental anxiety. Of course such a view does not seek to include those forms of cancer which are undoubtedly the result of mechanical irritation; it includes more especially the breast, and stomach, and, perhaps, liver and uterus—organs which are admittedly readily influenced by the condition of the patient's mind. Erichsen says: "Although the doctrine is incapable of proof, I cannot but look upon it as probable; we know by every-day experience that functional derangement of the abdominal and pelvic organs of the most inveterate character may be occasioned by mental disturbance, and it appears to me not improbable that such functional derangement may lead to perversion of nutrition terminating in malignant growth." It might be thought that all that the mental trouble did was to lower the general health; but cancer is not observed with anything like the same frequency when the general health is lowered from other causes, such as want. Many cases might be quoted in which the development of cancer has followed mental trouble in a singularly striking way; but no individual instance can go far in carrying conviction; it is rather the fact that the association is so very constant that carries weight. It is worthy of notice, too, that cancer is linked with insanity as the only diseases at present distinctly on the increase in this country. Now, I have brought forward only those diseases the dependence of which on mental causes seems to me almost beyond cavil, and in many of which the pathogenesis may reasonably be stated. Numberless other diseases and disorders have been asserted by various writers to depend on mental disturbance, and the cases they quote are often sufficiently striking. Among them are boils (Druitt) and dental caries (Marshall Hall). Variola and puerperal fever have been attributed to emotion, but I can find no reason to suppose that it renders persons exposed to contagion more liable to contract these diseases.

Pernicious anæmia.—Dr. Stephen Mackenzie has published three very striking cases where pernicious anæmia seems to have been caused by mental shock. In this connexion I might quote the views of Dr. Wilks, who says: "We hear sometimes of fear turning the whole mass of the blood; I believe this is literally correct. I have seen now so many cases of anæmia, some of them fatal, occurring upon a severe shock of the nervous system, that I have no doubt of the fact."

Many diseases, such as, for instance, rheumatoid arthritis or phthisis, depend on mental trouble only as one means of failure of general health. Other paroxysmal affections, such as asthma and megrim, undoubtedly often own mental shock as the exciting cause of individual attacks, and it seems that the development of paralysis agitans has a definite relation to some emotional disturbance. Purpura I have not mentioned, but one can readily credit that increased tension, due to mental cause, might be the determining agent in producing hæmorrhage. I need hardly, in passing, mention the frequent dependence of both amenorrhœa and menorrhagia on mental causes. Epilepsy is well known often to depend on mental causes; the fits are sometimes first excited by some great mental shock, while in other cases they begin gradually after long-continued anxiety. But epilepsy is not necessarily associated with organic changes; it is closely allied to insanity, and its only sequel is dementia, so I have not included it; it is rather a disease of the mind itself.

The subject I have dealt with would remain incomplete without a reference to two other striking conditions attributed to mental disturbance: they are fœtal malformation from emotion, and canities and alopecia from anxiety and fright. Of the former I quote just a few of the numberless recorded cases. A woman injured badly three fingers of the right hand in early gestation; the same three fingers of the right hand of the fœtus were arrested in development (Ormerod). A woman whose sympathy was much roused for her brother whose penis was completely amputated for carcinoma gave birth nine months afterwards to a boy whose penis was totally absent (Owen). Another woman during pregnancy saw a man with his right ear horribly mutilated; her child was born with no right ear (Mason). I might multiply such a list indefinitely, but I think I have given enough. Mr. T. Smith, in a paper on mothers' marks, mentions other striking cases, and says: "One cannot doubt that these marks occasionally appear on children in connexion with mental impressions received by the mother during pregnancy." Ten years ago considerable discussion seems to have been carried on in the medical periodicals as to whether the blood or nervous influence was the medium in such production; it seems to me exceedingly difficult even to have a theory as to the means, but the cases are so striking that I bring them forward. And, secondly, of alopecia and canities from fright and anxiety, the lines of Byron,

> "My hair is grey, though not from years,
> Nor grew it white
> In a single night
> As men's have grown from sudden fears,"

is no exaggerated dream of the poet. Complete canities and alopecia, sometimes all over the body, are undoubtedly brought about within a space of time to be measured rather by hours than by days under the influence of sudden grief or intense anxiety. Of course a large number of cases have been reported the evidence on which is not always complete and satisfactory. I am indebted to my friend Dr. Goodman of Kingston for directing my attention to the record of a case by Dr. Landois, in 1866, in which the blanching occurred in a single night, while the patient was under the daily observation of the physician. In this case microscopical examination showed that the hairs contained air-globules, and that there was no loss of pigment. It occurs without any evidence of impairment of general nutrition; the sufferer may not fail at all in his general health, and it is difficult to say in what way the change is brought about. To say that it is due to the fluid of the small capillary channels being absorbed does not get us much further; and such an effect on the hair is the more remarkable because we believe that growth of hair may continue not only during starvation, but even after death. In a number of THE LANCET published some forty years ago, I find a paper asserting most positively that in canities, subsequently to the transformation, there is a superabundance of calcareous matter in the hair, and that the effect depends on the quantity of lime in the system. It is

Digitized by Google

remarkable, and argues against the accuracy of this view, that it has not received confirmation and had importance attached to it; but assuming it to be true, the dependence of the quantity of lime in the system on mental causes is an equal mystery. Of all the striking cases that are recorded, the most remarkable is one recorded by Staff-Surgeon D. P. Parry, writing from Aldershot, who gives the case of a captured rebel whose hair turned completely white in half an hour under his own observation. I do not intend to include with alopecia due to these causes the disease known as "area"; it has not much in common with the alopecia I have alluded to, and in it there is at all events rarely any history of mental disturbance—certainly not more often than can fairly be regarded as a coincidence.

My inferences and beliefs will be open to the severest criticism, because from their nature they cannot be proved step by step in a method of true scientific deduction; they must necessarily be more or less a matter for individual belief. But I do think that we *may* be over-scientific. There are facts in life beyond those which can be established by science; there are finer mental actions which, though they produce even death, cannot be measured in the chemical balance or demonstrated by microscope. The physical reactions of mind on body have been too much neglected. I cannot doubt that the imagination has a substantial influence over organisation and function. I believe that on it often depends the efficacy of a remedy. I hope that I have done something to bring home the fact that mind and body are inseparable; that mental disease and bodily disease are inseparable. There are diseases of body alone and diseases of mind alone, but there are numerous other diseases where the two are closely coördinated—some where the mental disturbance is secondary to bodily disease, others where the bodily disease is secondary to the mental disturbance. Alienist physicians continue to thrash out the former class, but general physicians have too much neglected the latter. I am sure that the study of mental disturbance must afford to each practitioner of medicine not only most valuable indications for prognosis and treatment, but also no small field for that most conservative of all our duties—the prevention of disease in the recognition of its cause.

Bournemouth.

NOTE OF

A CASE WHERE A MASS OF LEAD WAS IMPACTED IN THE TYMPANIC CAVITY, AND REMOVED BY THE AID OF METALLIC MERCURY.

BY A. MARMADUKE SHEILD, M.B., F.R.C.S.,
ASSISTANT SURGEON AND SURGEON IN CHARGE OF THE AURAL DEPARTMENT OF CHARING CROSS HOSPITAL.

ON April 11th, 1892, I examined a tall, strongly built man, seventy years of age, who was a plumber by occupation, a native of Glasgow, and of the phlegmatic temperament and hardihood characteristic of his race. Six weeks before I saw him he was carrying a pot of molten lead down the ladder in a ship. The vessel gave a lurch, and he fell, the molten metal splashing over the side of his head and severely burning it. Some of the material ran down the right ear. The agony this caused was indescribable. He lay for five weeks in the Poplar Hospital. The burns improved, and the violent pain and inflammation of the ear were treated by warm and sedative applications. When the swelling had subsided, Mr. Williams, the house surgeon, detected some lead deeply embedded in the ear. Mr. Corner, under whose care the patient had been admitted, kindly transferred him to me for treatment, and I must here acknowledge my indebtedness to his courtesy for the opportunity of seeing and treating this very interesting case.

On examination, I found newly healed burns over the right side of the head. The patient was haggard and worn, and complained of constant pain and discomfort over the right side of the head, originating in the ear. An abundant offensive discharge flowed from the ear, there were ozæna and total deafness on the right side. The tuning-fork was heard long and loud in the mastoid, and the facial nerve was not implicated. On cleansing the ear and examining it, a mass of metallic lead came into view. It had burnt through and destroyed the drum, and filled the tympanic cavity, the surface of the lead being just flush with the remains of the membrane. The metal had also entered the Eustachian tube, for on inflating only a feeble current of air could be made to enter the tympanum. A preliminary examination with probe and elevator showed the mass to be quite firmly impacted — indeed, the metal had obviously accurately moulded itself to the inequalities of the tympanic cavity, which it completely filled. On April 12th, under good illumination, I made prolonged and cautious attempts to extract the lead, or at least to shift its position. I introduced a sharp and small, but powerful hook between the floor of the tympanum and the lead. This being turned round took a good hold of the soft metal, and I thus exercised an amount of traction which only the gravity of the case could justify. I was able to take firm hold in like manner of other irregular parts of the mass, but all attempts utterly failed to shift it in the least, and only impressed my mind still more with the firmness of its impaction. I next thought of using a drill and burrs, but was deterred by the risk of the instruments slipping at this great depth, and the presentiment that the soft metal would "choke" the instruments. It seemed that the only feasible method of removal would be by detaching the auricle posteriorly and chiselling away the posterior wall of the bony canal; an operation I was ready to undertake if the symptoms should have continued severe.

I next began to reflect on the possibility of reducing the bulk of the lead by solvents. In conversation with my colleague, Dr. Mott, we discussed this question, and, influenced by his suggestions as to the possibility of mercury forming an amalgam with the lead in the aural cavity, I made some simple experiments. On the night of April 12th I placed pieces of sheet lead in mercury, in solutions of iodide of potassium, in acetic acid, in chromic acid, and in carbonic acid. After twelve hours I examined the lead, and found the specimen that had been in contact with the metallic mercury brittle, soft, and much reduced in bulk, while the supernatant mercury was dark and lead stained. The next day the ear was well cleansed and the patient caused to lie upon his left side. The right ear was filled with liquid mercury, which he was asked to retain as long as possible. On the 15th I noted with satisfaction that when the mercury ran out of the ear it was mingled with lead, being dark-coloured, and a plumbic stain was visible on the walls of the canal. A symptom of significance was furnished by the patient also, who felt the mercury run down his Eustachian tube into the throat for the first time. He spat it up at intervals. He also declared that he could feel the lead move. The quicksilver was soaked into the ear for about sixteen hours in the aggregate. The following day I applied a syringe with a long nozzle to the upper wall of the canal, and induced a powerful jet. Scales of lead escaped, and then followed the mass, which fell with a "chink" into the receptacle. It was of irregular shape, resembling the contour of the tympanum, and coated with mercury. It was reduced in bulk, and all protuberances and angular projections before visible had disappeared.

The mercury had obviously acted as a superficial solvent, had reduced the bulk of the lead, and so allowed the stream of water from a powerful syringe to eject it. The inner wall of the tympanum could now be seen white and bare, apparently necrosed, while abundant granulations were springing from the posterior wall of the cavity. The treatment of perforative otorrhœa must be long carried out. The ossicles seem quite destroyed. The Eustachian tube is quite patent, and a powerful jet of air can now be passed through it.

Pouring of molten lead into the ear was a species of torture well known in the dark ages. I am not aware whether the victims afterwards became surgical patients. So far as I know, this case is unique. The treatment by liquid mercury is also, I believe, novel; and the possibility of employing this agent in cases of impacted bullets at once suggests itself. The case is an important addition to the subject of foreign bodies in the ear, and well illustrates the manifold difficulties which some of such cases present in their treatment.

METROPOLITAN HOSPITAL.

A CASE OF RUPTURED EXTRA-UTERINE FŒTATION; LAPAROTOMY; NECROPSY; REMARKS.

(Under the care of Dr. W. J. GOW and Mr. ANTHONY BOWLBY.)

THIS was apparently a primary case of tubal pregnancy, which had burst and formed a secondary attachment to the broad ligament and pelvic peritoneum, thus becoming secondarily an abdominal pregnancy. The date of rupture of the primary tubal pregnancy corresponds presumably to the attack of pain three months before admission; the fœtus must then have been in its fourth or fifth week. The sudden pain and collapse of two days' standing correspond to the rupture of the secondary abdominal pregnancy, and this agrees with the apparent length of time the fœtus had been dead. The history of pain eighteen months ago is probably that of the perimetritis which was found post mortem. The operation was undertaken of necessity at a very unfavourable stage, the patient being in a condition of collapse in consequence of the sudden rupture and hæmorrhage, but it was the treatment most likely to save the patient. For the notes of the case we are indebted to the house surgeon.

E. C——, aged thirty-seven, was admitted on Feb. 3rd with the following history. She had had one child fourteen years ago. Since then she had had no pregnancies, and menstruation had been regular up to three months ago. Eighteen months before admission she suffered from pelvic pain, which apparently passed off in a few weeks. Three months before admission she had several attacks of pain in the right iliac region, accompanied by constipation and suppression of menses. From this date she noticed a swelling at the seat of pain, and also thought her abdomen was increasing in size; this, together with the amenorrhœa, made her suspect that she was pregnant. About two weeks before admission she lost some bright blood, and two days before admission she had a sudden attack of severe pain in the right iliac region, with collapse, soon followed by vomiting, swelling of the abdomen, and absolute constipation. On admission the patient was collapsed and anæmic. She was constantly retching and was unable to retain food. Pulse 120, regular, but rather small; respiration 20; temperature subnormal. The abdomen was considerably distended and tympanitic except in the flanks, where there was impaired resonance. There was no fluid thrill. An indistinct mass was felt in the right iliac fossa. Per vaginam the os uteri was felt to be soft, and admitted the tip of the finger. The uterus was anteverted and displaced to the left side; the uterine sound entered three inches. Occupying the right upper half of the pelvic cavity a mass could be felt somewhat irregular in outline and about the size of a fœtal head. Bimanual examination was difficult owing to the rigidity of the abdominal wall. A smaller mass was felt in the left posterior quarter of the pelvis (ovary and tube). About 5 P.M. on the same day Mr. Bowlby performed laparotomy. On opening the peritoneum about two pints of dark-coloured blood escaped, and about a pint more was sponged out of the pelvis, together with many large clots. On exploring the pelvis the case was seen to be one of extra-uterine fœtation, and a large mass consisting of placenta and blood-clots was found behind the right broad ligament. This mass was partly covered by a membrane-like peritoneum, and through a large rent in this blood and clots were escaping into the abdominal cavity. The mass of placenta and clots was at once removed, and the cavity plugged with sponges. The removal caused but little bleeding. A second mass of blood clot with fœtal membranes and part of the torn umbilical cord was removed from behind the uterus and the left broad ligament. Finally, a fœtus was found free in the peritoneal cavity close to the left kidney. The age of the fœtus was about the end of the fourth month or beginning of the fifth, and it had apparently been dead about two days. All blood-clots and blood being sponged out as far as possible till the cavity was dry, part of the fœtal sac was sewn to the abdominal wound; but as the sac was extensively torn it could not be completely shut off from the peritoneal cavity. A drainage-tube leading to the fœtal sac was placed at the lower end of the wound. As it was thought advisable to finish the operation as soon as possible no washing out of the peritoneal cavity was attempted. Shortly after the operation there was some escape of blood from the drainage-tube. The patient progressed fairly well for sixteen hours afterwards, when she became rather suddenly collapsed, and died in about two hours. No further escape of blood from the tube occurred.

At the necropsy the following condition was found. The uterus was slightly enlarged and contained a loose decidua. There was old perimetritis on the left side by which the end of the left Fallopian tube was completely occluded and the ovary drawn down towards the uterus. The end of the right Fallopian tube was dilated and formed part of the fœtal sac. The main part of the sac was fixed behind the right broad ligament and attached to the posterior surface of the ovary, and also to a loop of the small intestine. The right ovary contained a true corpus luteum. The pelvic cavity contained about half a pint of blood, and several clots, some of considerable size, were found in the pelvis and abdomen. The fœtal sac had apparently ruptured along its whole upper surface, allowing the fœtus to escape into the abdominal cavity. The intestines were distended with gas, but there was no general peritonitis.

LONDON LOCK HOSPITAL.

CASE OF PHAGEDÆNA, WITH LOSS OF ENTIRE PENIS.

IT is not uncommon to meet with cases of sloughing of a considerable part of the penis as a result of the action of phagedænic sores, but it is rare to meet with a destruction of the organ to an extent here described. It was apparently due to a chancre concealed beneath the prepuce, which became rapidly phagedænic. The inflammatory swelling, the tension of the tight prepuce and retention of septic discharge, added to the patient's age, personal neglect, and recent debauch, seem sufficient explanation of its occurrence and extent. It is some weeks since the sore was first noticed, and no signs of constitutional syphilis have yet appeared. The fact that no hæmorrhage occurred on the separation of the organ can be explained on the supposition that thrombosis had taken place in the chief vessels of the stump, which were thus safely occluded after the one attack of hæmorrhage. For the notes of this case we are indebted to Mr. John C. Barrs, house surgeon.

G. B——, a carman aged sixty-eight, came to the out-patient department of the Lock Hospital on Aug. 29th, stating that three days previously he had made up his mind to consult a surgeon about a "venereal disorder" he had contracted; and was on his way to do so, when, feeling a desire to micturate, he discovered that his penis had dropped off. He had passed urine twenty minutes before through a hole in the side of the organ, and was quite unconscious of his loss until he tried to pass it again. His history was that five weeks previously he had exposed himself to the risk of contagion. Three days afterwards he felt a sore under the prepuce, which was swollen and red, and much discharge issued from underneath. The redness extended until it involved the whole penis, and in four or five days more it turned black. He micturated through a hole about half way down the organ. There was no pain. Seven days before applying to the hospital he had a profuse hæmorrhage from the penis, which he managed to arrest by tight binding. It was four days after the bleeding that the organ was lost. No bleeding occurred at that time, but his right leg was streaked with a grumous discharge. On first glancing at the region on admission, it appeared that the penis had been swept clean off, flush with the pubes, which was actually

Digitized by Google

the case. On close examination there was a small granulating protruberance, rounded off and somewhat mushroom-shaped, which was the remains of the corpora cavernosa. This, when made to project, by retracting the sheath around, was half an inch in length. Below, and cleanly dissected from the preceding, was the corpus spongiosum, with urethra, one-third of an inch long. The free end was very slightly contracted around the urethral orifice. Between the skin and the remains of the corpora cavernosa was a whitish, foul-smelling slough. No glands could be detected in either groin. No visceral disease was found on examination. The urine was pale and clear, of sp. gr. 1010, and contained no sugar or albumen. The patient had always possessed a long fore-skin, which he never retracted for purposes of cleanliness. He had not suffered from previous venereal disease, and had not sought professional advice before applying to the Lock Hospital. He had been drinking heavily of late. The slough separated in a few days, and the whole "stump" then cicatrised. The urethral orifice is not much contracted, and the patient is averse to any interference with it in the way of slitting it up and stitching it to the skin.

SALFORD ROYAL HOSPITAL.

A CASE OF COMPLETE EXTIRPATION OF THE LARYNX BY A SUICIDE.

PENETRATING wounds of the air passages are amongst the commoner class of injuries brought to our hospitals as a result of attempted suicide. This case is a very remarkable one, as indicating the amount of damage that a determined man can inflict on himself in such an attempt, and is worth recording for that reason. For the notes of this case we are indebted to Dr. R. E. Lord, house surgeon.

J. D——, aged fifty-eight, was brought to the Salford Royal Hospital at 4 A.M. on Feb. 25th, 1892. It was stated by his son that he had cut his throat an hour before with a potato knife, and that he had extracted from it a mass of gristle, which turned out to be the larynx. The patient was pulseless, but gave two or three gasps before he died in the accident room, five minutes after admission. On examination of the wound in the neck it was found to measure three inches across at its upper limit, which was formed by a triangular flap of skin which had been peeled up from the tissues. The right margin of the gap was also of triangular shape, its upper edge fitting on to the right edge of the upper flap and its lower on to the left margin of the wound, which was approximately straight and ran obliquely from above and to the left downwards, and to the right at an angle of about forty-five degrees to the horizontal line of the neck. On putting the finger into the wound the epiglottis was felt attached to the tongue, and the hyoid bone was *in situ*. The trachea had retracted about two inches below the level of the external wound. None of the great vessels were injured. The larynx, which had been brought by the friends, consisted of the thyroid and cricoid cartilages, the first ring of the trachea and the anterior half of the second ring. It measured two inches in front and one inch and three-quarters behind, from above downwards. On the right side, the upper border of the thyroid cartilage and the superior cornu had been cut off; and the ary-epiglottidean fold was divided at its posterior extremity, separating the right arytenoid cartilage, the cut extending slightly into the left fold. The right upper border of the thyroid showed three cuts, about three-quarters of an inch long, passing downwards and backwards, a piece of cartilage, one-eighth of an inch square, being completely cut out between the anterior and middle incisions. On the left side there was an incision in the cartilage passing downwards and towards the middle line for half an inch.

As regards the previous history of the case, there was nothing to point to any special delusion connected with the larynx. The patient had had an apoplectic seizure about a year before his death, and since then had suffered from right-sided hemiplegia with aphasia. The hemiplegia had improved considerably, but the aphasia had remained well marked. He had been very low-spirited for some months, but no delusions had ever been noticed, nor had he, as far as was known, ever threatened to commit suicide. It seems as if the patient had begun with the idea of removing, at all events, the prominent part of the larynx which he could feel in the neck, and to this end had made a right-handed incision, passing obliquely downwards and to the right, and then a second incision from the middle of this, passing upwards and to the right, and then peeling off the skin with his fingers. From the vertical cuts in the thyroid he seems next to have tried to cut off the projecting mass of cartilage; but, failing in this, to have cut in between the thyroid and the hyoid; then, having peeled off the larynx from the subjacent parts with his fingers, to have divided the trachea from behind, thus leaving two rings in front and one only behind.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Renal Dropsy.

AN ordinary meeting of this Society was held on April 26th, Sir Andrew Clark, Bart., President, in the chair.

Dr. DICKINSON gave a communication on Renal Dropsy, with especial reference to the circulation, together with some considerations relating to pulmonary apoplexy in renal disease. Although, as a general rule, the dropsy of renal disease varied inversely with the amount of urine, there were exceptions which suggested that other considerations must be introduced. Dropsy fluid was essentially the exudation from the capillaries which constituted the lymph. If too much of this was poured out or too little carried off dropsy resulted. There were two obvious agencies under which fluids passed through the capillary walls, and one which was hypothetical: (1) Filtration or transudation under pressure, acting on both colloids and crystalloids, albumen as well as salts; (2) diffusion or osmosis, acting on the salts, not on the albumen; (3) a secretory action on the part of the capillary wall, which had been inferred, but of which as yet we knew but little. The products of the first two processes must be different from each other, that of the third probably different from both. Dropsy fluids varied in composition more according to their position than their cause. Effusions in the serous cavities were always highly albuminous, though not equally so; œdema fluid was very slightly albuminous, whatever the disease to which it was due. The mineral salts were in much the same proportion whatever the place and cause of the effusion. If the albumen were the issue of filtration and pressure, these agencies were active in dropsy of every origin; if the salts were evidence of osmosis, this process was much the same in all. In obstructive suppression, where cardiac failure was obvious and low arterial pressure inferred, though urine might be totally absent, dropsy might be equally so. With nephritis dropsy was early and marked, arterial tension was increased, and the increase was borne out by early hypertrophy of the heart. The association of œdema and increase of tension were attributed to some condition of the capillaries due to abnormality of blood, which both hindered its passage and promoted transudation. This form of dropsy was commonly conjoined with obstruction in the lungs due to inflammatory change, but only a subordinate position was assigned to the venous retardation thus occasioned. Passing to chronic conditions a contradiction presented itself, for dropsy lessened with a further increase of arterial tension. This was commonly accompanied with increase of urine, but this did not necessarily remove dropsy, as was often seen in diabetes. Cases, tables, and cardiac diagrams were adduced in support of the position that the cardio-vascular change of advancing renal disease was the antagonist of dropsy. There was shown to be much dropsy with slight hypertrophy in nephritis; little dropsy and much hypertrophy with the granular kidney so long as the heart remained undilated; and, finally, on the stretching of the heart, increase of dropsy, and often pulmonary apoplexy. Pulmonary apoplexy was insisted on as a direct and simple result of advanced renal disease, irrespective of any lesion proper to the mitral valve. The relations of lardaceous disease to dropsy were considered, with the conclusion that this form of renal dropsy was brought about differently from that of nephritis and the granular kidney. The following conclusions were presented as not admitting of doubt: 1. Osmosis alone was not sufficient to account for dropsy, whether renal or of other kinds. 2. With the access of the dropsy of nephritis there was increase of

Digitized by Google

arterial pressure. With a further increase of arterial pressure as the disease became chronic, and cardio-vascular changes were established, there was diminution of dropsy. 3. Finally the heart gave way, and mitral regurgitation, pulmonary apoplexy, and increase of dropsy resulted. Further deductions, advanced less confidently, followed. The connexion between dropsy and uræmia was not simple, for the most extreme uræmia sometimes existed, while dropsy was totally absent. Neither had anæmia any necessary connexion with dropsy, though often associated with it. With pernicious anæmia dropsy was usually totally absent. With chlorotic anæmia there was sometimes slight œdema, but here another consideration intervened, for there was reason to believe that the pulse-tension was increased rather than diminished, and possibly a special poison and vascular obstruction were present. The relation of hydræmia to dropsy was also complex. Water had been injected into the vessels of an animal without producing œdema; and although slight dropsy resulted from the introduction of a large quantity of saline fluid into the veins of a diabetic patient, yet there was reason to believe that the effect was due rather to increase of intra-vascular pressure than to simple hydræmia. With the increased arterial pressure of nephritis, though neither the anæmia nor the hydræmia was as extreme as in other conditions, dropsy presented itself, and it was inferred that the process was essentially due to some change in the capillaries, produced by the state of the blood, of which obstruction and transudation were consequences. It was inferred that the obstruction belonged to the capillaries rather than to the arterioles. It was, of course, admitted that the aterioles were muscular and apt to contract, especially under nervous influences; but the capillaries would seem to be especially concerned in the process under consideration. What the nature of the capillary obstruction was must be left undeclared. Changes in the blood might affect its passage in many ways. Fluids of different sorts passed through inanimate tubes with different degrees of facility; besides which, the capillaries, though not muscular, had been demonstrated to be contractile. Proceeding to chronic disease and the granular kidney, the diminution of dropsy with the further increase of arterial tension required explanation. With this concurrence we had hypertrophy of the left ventricle, thickening and narrowing of the arterioles, and increase of urine. It was submitted that the constriction of the smaller arteries must cut off the blood from the capillaries, and presumably lessen pressure in them and exudation from them. Further, that the thickening of the ventricle must necessarily increase its expansile power and suction action, and thus draw upon the pulmonary circulation and relieve the veins and interstices. Next came the beginning of the end in the yielding of the ventricle, regurgitation, increase of dropsy, and often pulmonary apoplexy. Putting aside lardaceous disease, the points of resemblance and of difference between renal and cardiac dropsy came into prominence. In both the accumulation, as was well known, was essentially, however modified, that which exuded from the capillaries and constituted the lymph. Under heart disease there was diminished absorption without any presumption of increased exudation, or not to any important extent. Under kidney disease there was increased exudation without any necessary or constant diminution of absorption. Both were essentially connected with modifications of blood pressure—in one from obvious obstruction to the venous return, in the other from some presumably obstructive condition of the capillaries, which was attended with enhanced exudation from them, and associated with increased pressure within the arterial system.

Dr. GEORGE JOHNSON was not quite sure whether the author had modified the views he formerly held as to the function of the arterioles. Dr. Dickinson originally believed that the hypertrophy of the arterioles was simply in order the better to drive the blood onwards towards the capillaries, the impediment being really in the latter vessels. The question was whether the impediment to the circulation was seated in the arterioles or in the capillaries. He himself believed that it was in the arterioles. As to the main function of these vessels, it had been abundantly proved that they were the regulators of the blood-supply to the various tissues and organs. The phenomena observed during asphyxia threw much light upon their method of action, and he had fully set forth his views regarding this question in THE LANCET of April 4th and 11th of last year. Dr. Rutherford took a large dog, paralysed the voluntary muscles by a moderate dose of urari, and then opened the pericardium, the external carotid being divided and connected with a kymograph. As soon as breathing was suspended, pressure rose in the carotids, and the left heart, especially the auricle, became distended; later the right heart followed suit. Since then Dr. Rutherford's experiment had been repeated, with this addition, that the pressure in the pulmonary artery was gauged also, and it was found that when the pressure in the systemic circulation began to fall that in the pulmonary commenced to rise. He quoted some experiments to prove that the obstruction resided in the arterioles. Urari, atropine, and amyl nitrite, if introduced in sufficient quantities into the system, would all paralyse the arterioles. If a cat were urarised by the introduction of the poison into its peritoneum and the heart were exposed, with a kymograph in the carotid, as soon as artificial respiration was suspended the arterial pressure began to fall. If under artificial respiration the animal was restored for an hour, and meanwhile urine was passed (containing probably a considerable elimination of urari) it would then be found that when respiration was suspended pressure would rise in the carotid. The same result followed the introduction of atropine. Then, again, if nitrous oxide were inhaled the right side of the heart became distended, but with the administration of amyl nitrite the right-sided distension rapidly passed off. All these were decided evidences of the power possessed by the arterioles to impede the movement of the blood, and he knew of no evidence of this kind to prove a like power in the capillaries. Physiologists had admitted that young animals had some power of contraction of the capillaries, but this had not been proved to be true of the adult, and, even if it were true, it would surely not account for the great impediment to the circulation existing in Bright's disease. Even if it were admitted that they did contract to some extent, he failed to see how that explained dropsy through their walls, for the flow through them would be lessened. He believed that renal dropsy was the result of an active vital secretory process consequent on an accumulation of various morbid fluids and solids in the blood. As to cardiac dropsy, it was not as a rule much till the urine became scanty, and in this it resembled renal dropsy; it was not purely mechanical, but due to an accumulation of morbid substances in the blood. As to the access of dropsy in granular kidney, with the hypertrophy of the arterioles there came a hypertrophy of the left ventricle; and this increased ventricular power he believed might be great enough to compensate for the obstruction in the arterioles. He thought that the author attached too much importance to the mechanical view. As to pulmonary apoplexy, in the last stage of renal disease hæmorrhages were common from various mucous membranes, and they were the result of a blood disturbance combined with degeneration of the vessels. A copious hæmorrhage occurred into a bronchial tube, and not all was expectorated, but some was driven back into the smaller tubes and air cells; hence the apoplexy resulted. He summed up his views shortly as follows. That the arterioles could impede or arrest the circulation; that there was no evidence that the capillaries possessed a similar power; that there was no evidence of an increase of capillary pressure in renal dropsy, but probably that it was diminished; that it was difficult to explain effusion through capillaries mechanically, and that renal dropsy was best explained by regarding it as a vital act of the endothelium excited to eliminate certain noxious solids and fluids from the blood.

Dr. PYE SMITH, while admitting the weight of Dr. Johnson's views, held that the author had raised a much wider question than the part played by the arterioles or capillaries respectively. The method of the action of the arterioles was now established beyond controversy, and formed but a small part of the general question. He himself agreed with the author that cardiac dropsy was due entirely to pressure. As to osmosis, it was an affair of passive effusion dependent on the crystalloid or colloid character of the fluids dealt with, and was quite independent of pressure; but the transudation of fluids through membranes under pressure was a quite different matter. The mechanism of cardiac dropsy was clear. There was increased pressure in the small veins and capillaries, and difficulty of entrance of the lymph from the main ducts into the great veins. This constituted an obvious and complete explanation of the dropsy; but such an explana-

Digitized by Google

tion did not serve for renal dropsy. In that disease there were really two separate dropsies, the early or especially "renal," found with the large red or large white kidney, and then there was the dropsy of the later stages of granular kidney; the clinical characters of these two were quite different. The later one was "hydraulic" and cardiac in origin; it came on when the arteries were soft and the cardiac hypertrophy had given way to dilatation. The dropsy of obstructive cardiac disease and that of anæmia had probably a similar explanation. But the more proper early "renal" dropsy could not be explained in the same way. It might have some connexion with the secretory power of the capillary endothelium. Heidenhain had recently proved conclusively that this epithelium did possess an active selective influence, for he found that the introduction of certain substances into the blood would cause an increased flow of lymph independently of any rise in blood pressure. It might be ultimately proved that this was the case in renal dropsy, but the demonstration was yet to come. It certainly was not hydraulic, for in the early stages of an acute nephritis there was high blood pressure, but often no dropsy at all, and the dropsy would continue after the condition of high tension had passed off. Then the distribution of the dropsy showed that it was not subject to gravity. If it were not hydraulic, it was probable that it was not a dropsy at all, but an inflammatory effusion. Such inflammatory effusions were common in acute Bright's disease, the pulmonary œdema, the effusion into the pleura and the ascites were often inflammatory. He believed that the anasarca should also fall under this head as an active inflammatory change in the connective tissues.

On the motion of Dr. Sturges, seconded by Dr. Powell, the discussion was adjourned.

MEDICAL SOCIETY OF LONDON.

The Rarer Complications of Rheumatoid Arthritis.—Infective Endocarditis of the Right Side of the Heart.

THE last ordinary meeting of this Society for the present session was held on April 25th, the President, Mr. Hutchinson, in the chair.

Dr. KENT SPENDER of Bath read a communication on the Rarer Complications of Rheumatoid Arthritis. He had made an analysis of a very large number of cases which had been under his care during the last few years, and he had picked out certain unusual instances which illustrated in a marked degree some of the rarer complications of the affection. He alluded to the fact that the primary symptoms were not necessarily arthritic at all; there might be an unusual force and frequency of the cardiac beat; the skin might present patches of abnormal pigmentation; there might be irregular profuse perspirations, and but little might be complained of about the joints. It was not so much the osteo-arthritis as the grave dynamic commotions which accompanied it. In his classification of this disease he excluded the hip-ache of old people, and he likewise put aside the cases of septic arthritis. He then proceeded to detail at length the case of a lady sent to him in June, 1891, who presented arthritic trouble in a marked degree. Later the joint affection waned, but she began to complain of feeble action of the masseter muscles, of difficulty in protruding the tongue, and of progressive muscular atrophy of various muscles about the neck and trunk. She was seen by Dr. Buzzard, who recognised it as a case of neuritis with consecutive changes in the spinal cord; later, further degenerative lesions occurred. and Dr. Suckling of Birmingham, who saw her, regarded then the chief lesion as a scleroderma. The case went through three phases, being first a joint disturbance, then associated with profound nerve disorder, and finally trophic lesion of the skin. This suggested that the whole was due to a far-reaching neurosis. Some of the extreme cases of arthritis showed a profound disturbance of the circulation, the vagus not exercising its functions in its usual manner, the pulse being always above 120, though the patients had no palpitation or valve disease. In the major forms of this affection no good resulted from treatment, but in the minor cases the cardiac trouble diminished as the health improved. In other extreme cases there was a xanthoma as marked as in advanced cases of Addison's disease, and there would be a coming and going of small areas of discolouration like bruises on the affected limb. Then followed a common atrophy of both muscle and skin: in some there would be a to-and-fro spasm of one arm with an extremely cold, damp hand, glossy skin, and athetotic movements. In other cases neuralgia was a marked feature, the pain being often in inverse proportion to the weakness, and there might be gastric crises which marked a kinship between rheumatoid arthritis and locomotor ataxy. Lastly, there might be vaso-motor derangements of an extreme type, involving both limbs and viscera. He advocated the early use of the dynamometer as being a ready indicator of approaching muscular weakness. His conclusions were that rheumatoid arthritis was from its history and symptoms to be regarded as a disease of the nervous system; that it might receive an impulse from rheumatism or gout through either the nerves or the bloodvessels; that when fully developed it possessed what might be called an arthritic cachexia; that this cachexia was associated with diminution of nutrition, atrophy, and errors of nerve control, and that if taken early it might be ameliorated or cured; but later it became entirely unmanageable, and as intractable to treatment as a malignant disorder.—The PRESIDENT questioned the advisability of using the term "rheumatoid arthritis," and he thought that some of the cases quoted as examples of complications were really instances in which other maladies joined with the arthritis in producing a multiple disorder. The vaso-motor system took a share in the production of almost all diseases, but it was excessively difficult to say whether it exerted the primal influence in departure from health. He believed that the old term "rheumatic gout" was still the best for this group of cases; on the rheumatic side it proceeded from a nervous and on the gouty side from a blood origin.—Dr. ORD thanked the author for bringing forward his interesting considerations regarding osteo-arthritis, which, however, he preferred to regard not as an objective disease, but as a symptom belonging to a number of conditions; whether we were studying or treating the malady, the latter was the most philosophical standpoint. This characteristic condition of osteo-arthritis, whether overgrowth or atrophy, was met with in varying conditions; in gout, after acute rheumatism, in affections of the nervous system, either as a direct sequence of lesion in the anterior horns of the cord, in pachymeningitis, peripheral neuritis, or lead poisoning, or in association with internal mischiefs not originally of nervous origin, such as congestive uterine affections &c., in lesions of the prostate and adjacent urethra. It might be associated with injury of a joint, either sudden, as a blow, or more gradual, as in chronic strain, or with injuries of bones near joints, the latter not being affected. He was not prepared to say how far sepsis should be included as a cause. The first thing was to recognise that the joint affection might occur in a large number of conditions, and then so far as possible to recognise the conditions which surrounded each. In the case quoted by the author at length there was the osteo-arthritis followed by the spinal trouble and the so-called scleroderma, but this sequence had often been noticed in cases of chronic anterior poliomyelitis and of chronic spinal pachymeningitis, and in peripheral neuritis likewise. In conclusion, he thanked the author for the interesting account he had given of such correlative symptoms as abnormal pigmentation and local perspirations.—Sir DYCE DUCKWORTH would confine his remarks to one aspect of the question. He held the view strongly of the nervous origin of this affection, and he admitted that many conditions might lead up to the disease. He hoped that the therapeutics of the author were not those of despair. Many cases, no doubt, were tedious and intractable, but in many amelioration could be brought about by treatment directed towards invigorating the nervous system and the local application of thermal waters.—Dr. BLAKE thought that the Bath school should have helped more in elucidating the pathology of the rheumatisms, and he enumerated in what he considered to be the order of frequency the most common causes of rheumatism in males and females respectively. He had seen the same poison give rise to the three manifestations of rheumatism, chorea, and urticaria in the same subject. He felt sure that sepsis played a large part in the production of tachycardia.—Dr. SANSOM, referring to the Presidential remarks, said that undoubtedly the term "rheumatic gout" was good in a certain class of cases in which the symptoms of both were commingled, but those were not under discussion in the paper. The author was referring to such cases as the following:—A middle-aged woman would present vague symptoms, palpitations, gastric crises, and anomalous kinds of pain

Digitized by Google

here and there; then changes in the joints might be found, such as thickenings of the knuckles in which there was no pain. One then went more deeply into the case, and found that the heart was unusually quick—not paroxysmal, but constant, and persisting for years; in other cases it was markedly irregular; in all, arthritic phenomena would be found unaccompanied by uratic deposits. Such cases were a strong argument in favour of a change in the central nervous system. It was unlikely that the cardiac condition was due to an irritation of the accelerator mechanism, but it probably followed an alteration of the relation between the vagus and the sympathetic, and the cardiac action thus resembled the exaggerated reflexes seen when certain parts of the nervous system were cut off from the control of the higher centres. The term "osteo-arthritis" might not be well chosen, but it served to indicate the joint lesions which followed changes in the central nervous system.—Dr. ARCHIBALD GARROD agreed that the ulceration of cartilage &c. should not be looked upon as a disease, but as a symptom; and the various conditions which the author had enumerated as complications should rather be looked upon as morbid associates, all being due to a central cause. As to the local sweatings and pigmentations, these and other symptoms were far from being constant; pigmentation especially was common in elderly people who were not affected with osteo-arthritis. The influenza epidemic appeared to have materially increased the amount of osteo-arthritis, and in cases where the disease had already commenced it had been made much worse.—Dr. KENT SPENDER, in reply, said that he saw from 200 to 250 fresh cases of this affection every year, and out of this mass of material he had compiled his paper, selecting especially the very extreme and unusual types. Numberless other cases, though they presented one or more of the symptoms alluded to, only showed them in a slight degree; called them "connoting" symptoms because they helped to a diagnosis. In only about one case in ten would none of them be present.

Sir DYCE DUCKWORTH contributed a paper on a case of Infective Endocarditis of Right Side, with Pneumonia and Cerebro-spinal Meningitis. The patient, a potman aged twenty-eight, of intemperate habits, was admitted into St. Bartholomew's Hospital on June 25th, 1891, for severe pain in the chest. On June 21st he shivered, and suffered from dyspnœa and cough. Next day he was worse, with increase of pain, and took to bed. Another shivering occurred, and all his symptoms being aggravated, he was sent to the hospital. The family and personal history were unimportant. There was no history of the occurrence of rheumatic fever. On admission, the patient was found to be fairly well nourished. The face was flushed and dusky, and the large veins turgid; there was some painful cough and dyspnœa; the skin was moist, alæ nasi dilating, and conjunctivæ icteric; no herpes on the face; tongue thickly furred posteriorly. Great pain was complained of on the right side of the chest. The temperature was 102°, respiration "catching," 48, and the pulse 140 soft. Loss of appetite. The chest expanded feebly. Percussion-note fairly good under each clavicle, dulness in the right axilla. Over the right front, double friction audible and faint bronchial breathing, especially with expiration. The left front was also dull at the level of the sixth rib, and in the axilla, and friction and doubtful pleuro-pericardial friction were audible. Posteriorly, both bases were dull as high as the lower angles of the scapulæ, with impaired note as high as the spines. Bronchial breathing, friction and bronchophony audible, and very few crepitations. The sputum was tenacious and of greengage-plum colour. The heart's apex was just inside the left nipple line. The sounds were clear. No increase of cardiac dulness noted. The abdomen was natural. The extremities rather dusky looking. Moisture in the palms of the hands. Some diarrhœa was present at first.—June 26th: Delirious during previous night, but not noisy. Temperature rose to 102·4°. Took nourishment well, including six ounces of brandy. A mixture with quinine, digitalis, and nux vomica was given. The pulse rose to 144, and was occasionally dicrotic. Sputa became more rusty in character. Carphology was noticed.—27th: Less delirium. On this, the seventh day, an apparently critical fall of temperature occurred, 98·6° being reached in the morning; but the pyrexia was not checked. Redux crepitation was noted in the chest. Pulse dicrotous. Some apparent improvement was observed for the two or three following days, the temperature averaging from 101° to 102°, but the pulse continuing rapid. Nourishment was well taken. Subsequently there was a return of delirium, and urgent dyspnœa supervened with signs of carbonæmia. Strychnine was employed hypodermically, and ether freely given. Oxygen gas was also inhaled, but without any benefit. Shortly before death on July 6th, the sixteenth day of the illness, some convulsive seizures occurred. The highest temperature was recorded on the fourteenth day, 103°. At the necropsy there were found a few adhesions in both pleuræ, with general engorgement of the lungs. In the right lung irregular consolidation of the base, and towards the centre of this an abscess the size of a pigeon's egg. Red hepatisation at the base of the left lung. There was no pericarditis, and no hypertrophy of the heart. On the auricular surface of the tricuspid valve was found a large irregular botryoidal growth, equal in size to three or four small grapes, soft and friable. It was dark grey in colour, and already putrid. In the abdomen were some adhesions about the spleen, which was large and soft, but free from infarcts. The liver was swollen (75 oz.), pale, smooth, and fatty. The kidneys were large and engorged. At the base of the brain was found an exudation of lymph, extending into Sylvian fissures, between the two halves of the cerebrum and down the spinal cord. Ventricles dilated with sero-purulent effusion. Brain substance soft. In this case a correct diagnosis was not arrived at during life. The signs and symptoms agreed with those which might be expected in a case of double pneumonia in a drunkard. Nothing pointed to any cardiac disease, the heart sounds being clear whenever examined. The delirium and adynamia were not remarkable in such a case, nor were diarrhœa and carphology. The rigors were confined to the early days of the illness, and there were none after admission to the hospital. The enlarged spleen was not detected during life. There were no marked sweatings or high flights of pyrexia, the highest temperature being reached on the fourteenth day. Death occurred on the sixteenth day, and was only preceded by convulsive seizures, which were apparently due to carbonæmia. No plain indications of cerebro-spinal meningitis were observed. The necropsy threw a clear light on the case, and showed that the pneumonia was septical, and that the nervous symptoms were in part, at all events, due to septic or infective cerebro-spinal meningitis. The saprogenic mass in the right auricle was too decomposed to allow of any profitable quest after specific micro-organisms. It was urged that cases of this nature might probably often escape detection during life, where instances of infective endocarditis involving the left chambers of the heart could now hardly escape recognition owing to more obvious and widely spread results. The origin of the disease remained in doubt and obscurity.—The PRESIDENT referred to a drawing in his possession taken from a case of osteitis, in which there was pus beneath the endocardium of the right heart, together with ulceration.—Dr. BENHAM imagined that it was a case of pyæmia due to absorption from some focus. He asked if the ears were carefully examined at the necropsy.—Dr. GASTER alluded to a case which had been published which was much like that related. The patient had been under treatment for some joint mischief when a fatal pneumonia developed. Right ulcerative endocarditis was found, and the lung was riddled with abscesses.—Dr. SANSOM said that attention had been called to the connexion between septic pneumonia and endocarditis, and also between osteomyelitis and ulcerative endocarditis. The right side of the heart was certainly disproportionately involved in these cases; in some probably the organism was carried to the heart by way of the lymph circulation.—The PRESIDENT added that as osteomyelitis was essentially endophlebitis, it was easy to understand why the right side of the heart should be affected in these cases.—Mr. SHEILD had seen a number of cases of acute necrosis which were often mysterious in their onset, being mistaken for rheumatism because of their joint effusion and pericarditis. The condition of the heart was probably always secondary to that of the bone. The occurrence of hæmaturia might be expected owing to renal embolism, and gangrene of the limbs might likewise result.—Dr. CHAPLIN said that he had shown recently at the Pathological Society the pulmonary valve of a heart affected with ulcerative endocarditis, there being exuberant vegetative growth. There were small vegetations also on the tricuspid and aortic valves. The temperature was very high, and the lungs were pneumonic and contained infarcts.—Sir DYCE DUCKWORTH, in reply, said that there was no history of ear disease. The case was difficult to recognise during life because there were no symptoms attributable to the heart.

CLINICAL SOCIETY OF LONDON.

Cirsoid Aneurysm of Eyebrow.—Syphilitic Disease of both Knee-joints.—Neuritis following Fracture of Arm.—Myxœdema treated by Injections of Thyroid Juice.—Sequel to Case of Myxœdema.—Ligature of Common Carotid for Hæmorrhage after removal of the Tonsil.

A "CLINICAL" MEETING of this Society was held on April 21st, the President, Sir Dyce Duckworth, in the chair.

Mr. G. R. TURNER first introduced a girl aged sixteen, the subject of a Congenital Pulsating Tumour of the Forehead of doubtful nature. He regarded it either as in part a venous nævus associated with a cirsoid condition of the temporal artery, or as an aneurysm by anastomosis. It occupied the greater part of the right eyebrow and eyelid and the right side of the forehead, and there were distinct pulsation and thrill. It was fed by the anterior branch of the temporal artery; the supra-orbital was not apparently implicated.

Mr. TURNER next showed a sailor aged forty, who had been an inmate of the Seamen's Hospital with disease of both knee-joints, simulating tubercular arthritis. There were likewise signs of breaking down at the left pulmonary apex, and there was effusion into both ankles and into the left elbow-joint. He had a chancre fifteen years ago, but there was no history of secondary symptoms. After his admission he suffered from ulceration and sloughing of the palate, and this led to the administration of anti-syphilitic remedies, with the result that the trouble in all the joints disappeared except the right knee, which remained in an ankylosed condition. He regarded it as an instance of gummatous deposit about the synovial membrane, and the case was interesting as showing how syphilis could imitate tubercular disease.

Mr. LUNN brought a woman aged thirty-eight, who, in June, 1891, sustained a Comminuted Fracture of the Right Humerus. On examination six months later there was an inch shortening, and the lower end of the humerus was much thickened. Pain was complained of shooting down both sides of the forearm, and there was numbness in the fingers supplied by the median nerve, with weakness of the muscles, especially the flexors. In February he cut down on the prominences over both condyles and removed spicules of bone which were pressing on the median and musculo-spiral nerves. The patient had since lost the numbness of the fingers, and muscular power was returning.

Dr. ARTHUR DAVIES exhibited a woman aged sixty-two, who was the subject of well-marked Myxœdema. The disease began more than two years ago in the eyelids and feet. There was no albuminuria.

Dr. DAVIES likewise introduced a man aged forty-three, who had suffered from Myxœdema since 1879, and had been for some time under the president's care. Since last December he had been injected in the back three times a week with half a drachm of sheep's thyroid juice prepared according to the formula published in the *British Medical Journal* of Oct. 10th, 1891. The injections caused a gradual rise of temperature, followed by diuresis, and they had produced a very remarkable improvement in the man's condition.

Sir DYCE DUCKWORTH read the sequel to a case of Myxœdema already reported to the Society, with an account of the post-mortem examination. The first part of the case was related in November, 1880, and the patient, a women aged fifty-seven, came in for the third or fourth time to St. Bartholomew's Hospital in May, 1891. The earliest signs of myxœdema began about 1876, and her case was observed at intervals for eleven years. There was progressive enfeeblement, and gradual onset of most of the well-recognised symptoms of the disease. Some improvement always followed her sojourn in the hospital. The temperature was commonly subnormal, and there was an intractable condition of gastric catarrh and dyspepsia, with a tendency to diarrhœa. The features became more and more bloated, and the hands larger and more clumsy. The hair fell off, and left a spare and very coarse covering on the scalp. The voice became very hoarse and guttural, and the speech very slow. The skin was harsh and dry. The knee-jerks were first noticed to be absent in February, 1891. Plantar reflexes were normal. A little albumen was constantly present in the urine, and the urea was several times found to be excreted at the rate of 1 per cent. The teeth fell out. The rectum became much loaded, and ptyalism occurred with much anal excoriation. Bronchitis set in finally. At the necropsy there were found few noteworthy changes in any of the organs. The arteries were somewhat thickened. Many superficial circular ulcers were found in the cæcum and colon, coalescing in places into irregular patches (probably so-called distension ulcers). The kidneys were slightly granular, and weighed together 11 oz. There were submucous hæmorrhages in the bladder. The uterus was natural, and the ovaries firm and white. Some dilatation was found in the central canal of the cervical portion of the spinal cord. The thyroid body was small, white in appearance, and weighed two drachms and a half; it was natural in shape. It was contrasted with that from another body examined at the same time, which weighed five drachms and a half. The whole duration of the case might be reckoned at fifteen years, and might possibly have been longer.

Mr. ARBUTHNOT LANE gave the clinical details of a case of very severe Hæmorrhage following Removal of the Tonsil, in which ligature of the common carotid and transfusion were followed by recovery. The patient was a man aged twenty-one, who had his tonsil removed at the Throat Hospital on Dec. 16th. At the time of the operation, and during the few hours following, he lost about half a pint of blood. On Dec. 19th he lost another half pint. Bleeding recurred on the evening of the 20th, and continued steadily in spite of local applications. He was urged by Dr. Herron, his medical attendant, to go to the hospital, but refused. Mr. Lane saw him on the 22nd, when, as he was evidently dying, his friends consented to his removal into Guy's Hospital, a distance of only a few yards. He was carried directly into the operating theatre from his house on a stretcher. As he was in such an extremely collapsed condition, normal salt solution had to be introduced freely into the circulation before any other operation could be done. He reacted at once to the injection, when Mr. Lane tied the common carotid. It was not necessary to inject more than three and a half or four pints of salt solution, his pulse being then 96, large and full. He left the hospital within a few days, quite well. The point of interest about the case, besides the perfectly successful result of the saline intravenous injection, was the delayed onset of the bleeding, which recurred more than four whole days after the excision of the tonsil. On carefully examining the excised area after the operation, as the patient's condition did not admit of it before, no evidence of any injured vessel could be seen. The tonsil had been very freely removed, but probably not more so than is very commonly done. There was nothing in the man's history or in the behaviour of the wounds at the time of the operation which suggested that he bled more readily than other people.—Mr. HARRISON CRIPPS, while congratulating the author on the success of the operation, said that according to his view, while the result was good, the surgery was bad. Though it might be impossible to seize the bleeding points and to apply pressure, yet it was not good surgery to tie the common carotid, which gave the worst results of any artery when tied for hæmorrhage. Half died from brain symptoms, either at once or later from softening, and a considerable number perished from recurrence of the bleeding. The chief blood supply for the tonsil arose from the external carotid, which should be tied between the superior thyroid and lingual, and after its ligature recurrent hæmorrhage was very rare indeed.—Mr. HULKE congratulated the author on the success of his treatment. Mr. Cripps seemed to think that it was impracticable to apply pressure to the tonsil, but this could be efficiently done by means of a pair of long-bladed forceps padded with lint, one limb being passed inside the mouth and the other resting opposite to it outside the neck. Though it might be better to tie the external carotid, yet that operation took longer, and the condition of the patient might be so urgent as to drive the surgeon to ligature the common vessel.—Mr. LANE replied that he had found no difficulty in controlling hæmorrhage from the tonsil by means of digital pressure. In the case under consideration he exposed both the external and common carotid in his incision, but he found that a large ascending pharyngeal was present, and that the branches of the external were arising very close to its origin. He therefore had no alternative but to tie the common carotid. He had had no cerebral trouble after ligature of this vessel, because in the cases in which he had done so he had always injected salt solution, and he believed that if a similar practice were carried out in all such cases it would abolish this complication.

Reviews and Notices of Books.

A History of Epidemics in Britain. By C CREIGHTON, M.D., M.A. Demy 8vo, pp. 706. Cambridge University Press. 1891.

THE syndics of the University Press are to be congratulated on the publication of this work. The first of its kind in this country, it is not only a monument of industry and erudition, but is marked throughout by a scientific discrimination strongly contrasting with the credulity of some previous workers in the same field. The labour of the medical historian is far more difficult than that of the politician or statist, his materials are more scanty and less palpable, while learned and vulgar ignorance and superstition, erroneous diagnosis and fossilised theory, confused conceptions and ambiguous expressions, the verbalism that reigned supreme for centuries, and the changes of meaning that the most familiar terms have undergone, present obstacles and pitfalls from which other fields of history are free. But while Dr. Creighton has avoided these sources of fallacy with consummate skill, and has elicited his conclusions from the most unsatisfactory materials, truth compels us to recognise in the work a manifest bias towards a theory of the nature of specific and infectious disease, not in agreement with the opinions of the leaders of modern epidemiology. He adduces ample and irresistible evidence in favour of the influence of fluctuations of the ground water, in determining the outbreaks of disease, which has been insisted on by Pettenkofer; but it is significant that from the first page to the last there is no mention of or allusion to bacteria.

It would be a labour lost for us to enter here on a defence of bacterial pathology, but *fas est ab hoste doceri*, and we frankly admit that the author has brought forward much evidence from which the reader may learn to modify, or rather to perfect, his theories. Without bating one iota from our belief in the essential connexion between bacteria or their products and disease, we may—indeed we must—with him, recognise evolution as a factor in the etiology of even the most specialised of these diseases, since the alternative hypothesis of their origin in separate creative acts is at once improbable and utterly unscientific. Reading thus between the lines, and interpreting "the gradual transition of one form of disease into another, with the rise of new diseases *appropriate* to new material and social conditions" as processes of evolution whereby bacteria acquire new characters under altered surroundings, we shall find his views on the relations of typhus fever and plague, of dysentery and yellow fever, and, though more speculative, of ecthyma and small-pox, in the highest degree suggestive and fraught with instruction. Dr. Creighton takes as the termini of the "Middle Ages" the two greatest plagues the world has ever seen—that in the reign of Justinian, A.D. 542 and the following years, and the black death, which ravaged this country in 1348 and 1349. The former did not reach these islands until the seventh century, while the latter was pandemic. But for 700 years pestilences were in this country constantly associated with famines, especially in the terrible period that elapsed between the Conquest and the accession of Henry II. Civil wars were frequent enough; but as Philip de Comines observed of the Wars of the Roses, England enjoyed "the special grace" that the only sufferers were the actual combatants, the nobles and their armed retainers. It was only in the earlier years of the struggle between Charles I. and the Parliamentary forces that war was attended by pestilence, as it always was on the Continent—a combination of horrors which reached its climax in the Thirty Years' War. Ergotism was also almost unknown in this country, where rye or "black" bread has never been the staple food of the common people. The "sidelights" thrown on the history of the people in the consequences of famines and pestilences seen in the altered circumstances and relations of the several classes of the community are of far wider interest.

The chapter on Leprosy is extremely interesting, inextricably mixed up as are the contemporary notices of this disease with syphilis and with all kinds of cutaneous affections. This is indeed implied in the Levitical instructions for its diagnosis by the Hebrew priest; but scriptural associations gave a sentimental or religious glamour to the disease, and the sufferers or "pauperes Christi" were the objects of special legislation and of lavish charity, in which, no doubt, syphilitics and impostors enjoyed a large share. Though naturally shunned by society, their segregation was due rather to the repulsive character of the disease than to any belief in its contagion—a belief, in fact, held in respect of those forms only which we can now clearly recognise as venereal. From these various causes the amount of true leprosy in England at any time has doubtless been greatly over-estimated. Dr. Creighton ridicules the notion of its having been imported from the East, and finds its origin in the use of coarse and unwholesome food, especially of decomposing and ill-cured flesh or fish, together with "misery" of every kind—drawing a parallel between leprosy and pellagra, which is well known to be connected with the consumption of spoilt and mouldy maize by the indigent peasantry of Lombardy and Roumania.

The Black Death was like the pestilence of Justinian's age, the bubonic plague in an intensified form, though presenting in its distribution and incidence some points of difference from other epidemics of the same disease. Dr. Creighton's theory of the origin of plague virus, deduced from a mass of evidence ancient and modern, gathered from mediæval Europe, from Egypt and Arabia, from India and China, is, that while filth and famine tend to generate spotted typhus fever, the bubonic plague has constantly been associated with cadaveric pollution of the soil, whether from the accumulation of unburied corpses after inundations or devastating wars, or from superficial interment, or from intra-mural sepulture carried on through a long succession of generations. Among the results of the depopulation effected by the black death was the mobilisation and consequent enfranchisement of the agricultural classes, whose material prosperity was never so great as in the following or fifteenth century, notwithstanding the civil wars; their subsequent pauperisation coinciding with the commercial development of the nation and the enclosure of common lands by the nobles, who, under the Tudors, turned their attention from domestic feuds to the cultivation of the arts of peace. The plague remained endemic, with epidemic outbursts from time to time, until about 1667, when it abruptly and unaccountably disappeared; certainly not in consequence of the Great Fire, since it had been far more severe in the out parishes than in the city, and in some provincial towns than in the metropolis itself. It is strange, too, that while attention was constantly directed by the authorities and the medical profession to surface filth as a cause of fever and plague, the saturation of the soil of London with the products of putrefying corpses seems never to have given rise to misgivings.

The Sweating Sickness will always remain an insoluble riddle, alike in its etiology and pathology. It first appeared in England in 1485, and it vanished from the earth in 1551. Each of its five visitations was of short duration; they were separated by intervals of from eight to twenty-three years; it fell mostly on the well-to-do classes, and the fatality exhibited the widest differences. It did not appear on the Continent until 1529, and, while it ravaged the Netherlands and Germany; France, Italy, and Spain escaped. It

Digitized by Google

was in, fact, confined to England for forty-three years and to the Teutonic race for the next twenty-three.

It is a curious historical coincidence that registration and sanitary legislation have attained their highest perfection in the reign of our present Queen, the prime motor having been the invasion of cholera, whilst it was under Queen Elizabeth that, in view of the prevalence of plague, the first systematic attempts at these measures were undertaken by the company of parish clerks or choristers, who were at once registrars of christenings and deaths and sanitary inspectors. The "gaol fevers" or outbursts of typhus fever which marked the several "black assizes" of the Tudor period presented in some instances, though not in all, the remarkable phenomenon of men, who, though subjected to insanitary conditions of the most aggravated kind, had not manifested any signs of a definite disease, but who infected healthy persons almost immediately with a fever of the most virulent type—a paradox to which we shall refer in connexion with the origin of yellow fever.

Much obscurity surrounds the stories of epidemics of those times, even after English physicians began, in the sixteenth and seventeeth centuries, to write from their own observation, instead of servilely reproducing the works of foreign authorities. The name "influenza" was not naturalised in this country until the eighteenth century; ague fevers was the vernacular for *febres acutæ*, with no connotation of periodicity; measles once meant persons suffering from skin diseases (*miselli*, diminutive of *miseri*); and even later we find small-pox and measles used indiscriminately for variola and morbillæ. The confusion between the great-pox and small-pox, or between syphilis (which was formerly mixed up with leprosy) and variola, is no less embarrassing. No doubt syphilis is coeval with venereal debauchery, but the earliest accurate descriptions and recognition of its specific character are connected with the epidemic of 1494. When popularly associated with the invasion of Italy by Charles VIII. of France it acquired the designation of the French pox.

For the early history of small-pox we are indebted to the Arabs, from whom we learn with certainty that it appeared among the Abyssinian troops at the siege of Mecca A.D. 570. Dr. Creighton is inclined to look on it as an evolution from ecthyma under the conditions presented by the people and climate of Africa, and draws a parallel between it and the yaws. He does not, however, seem to be acquainted with the early accounts of small-pox in Hindoo writings. But recent outbreaks of epidemic ecthyma in Africa, to which he refers, are in favour of his theory. At any rate there is no doubt as to small-pox having been brought into Europe from the East by the Crusaders, though there is no direct evidence of the existence of small-pox or measles in England before the fifteenth or sixteenth centuries. Kellwaye, however, in 1593, gave unmistakable directions for the differential diagnosis of the three diseases which we call variola, varicella, and measles.

The history of Sea Scurvy begins with the long voyage of which that of Vasco di Gama in 1498 was the first. It offers nothing remarkable except the account of a disease which broke out among the crew of the *Desire*, under Cavendish, in 1588, in consequence apparently of their having been driven to subsist on badly dried and rotten penguin flesh. It was not true scurvy, and Dr. Creighton sees in it a nearer resemblance to beri-beri. The origin of yellow fever is one of the most interesting questions in epidemiology. It is intimately connected with the history of the slave trade, and dates from 1647. Dr. Creighton's views are not new, having been already ably propounded by Hirsch. He adduced a great deal of evidence bearing on the subject. Though a soil poison, bred in the mud of the stagnant lagoons and estuaries of the West Indian Islands and the shores of tropical America, limited in its extension by temperature &c., it is not a malarial fever proper, or indigenous to the countries. Its foci are exclusively those harbours which have been the centres and ports of debarkation of the slave trade, to which it owes its existence; yet the negro race enjoys complete immunity. The only explanation is that on those muddy shores where the slave ships were careened, and the bilge water, dysenteric ordure, and filth of every kind were discharged, with no tides to carry them out to sea, a new disease was developed, and the microbes of dysentery acquired new characters and powers fatal to the European constitution but against which the negro is immune. Dr. Creighton does not refer to the fact that negroes, when compelled to adopt the use of soap and water in place of their customary greasy inunction, are by no means proof against malarial influences; but he points to the still more striking fact that the most pestilential mangrove swamps and lagoons are free from yellow fever, provided they have been innocent of the importation of negro slaves. In short, where typhus fever has been cultivated in the soil it is transformed into bubonic plague, and where the dysentery of negroes during the horrors of the voyage has been cultivated in the warm brackish mud, it develops into yellow fever—a disease of the white man alone; and the cultivation theory is probably capable of throwing light on the origin and evolution of other specific and communicable diseases.

OUR LIBRARY TABLE.

Report on the Social Economy Section of the Paris Universal Exhibition of 1889. Prepared by JULES HELBRONNER, Member of the Royal Labour Commission, and printed by order of the Canadian Parliament at Ottawa, Canada.—There is always this inconvenience about international exhibitions and congresses, that the reports relating to the same appear so long after the event as to seem out of date. Nevertheless, there is no denying the value of facts, especially such as those contained in the volume before us. Most of these relate, it is true, to the economic rather than to the hygienic condition of the working classes in the civilised countries of the world; but there are chapters especially devoted to the laws and institutions that directly affect health. Also it is impossible when dealing with the working classes and all those who only possess very small incomes—and this represents the enormous majority of the population of all countries—to separate the economic from the sanitary problem. What is the use of model artisans' dwellings if the artisans do not earn enough to pay the rent for such dwellings? Consequently, even the chapters of this volume which deal purely with economics give information that is most useful to the sanitary reformer. They show what efforts have been made by profit-sharing, coöperation, trades unionism, by philanthropic effort, and by laws and legislation to improve the economic situation of the poorer sections of the community in a great variety of countries. A very rich collection of facts substantiated by official documents is given. Then there are chapters devoted to such questions as the housing of the working classes, where an account will be found of some of the most celebrated continental building societies. Other chapters deal with the various methods employed and organisations existing for the prevention of intemperance. There is also a short account of the International Congresses on Cheap Dwellings; on Accidents in Workshops, Factories, &c., and on the Intervention of Public Authorities in Economic and Sanitary Matters. As an example of the sort of information to be found in this volume we may mention that, according to the evidence given by Dr. Du Mesnil, inspector of lodgings, the mortality in a quarter of Paris where but 9 per cent. of the lodgings were producing

Digitized by Google

under £12 rental amounted to 14 per 1000 of the population. In another quarter, where 59 per cent. of the lodgings are worth less than £12 a year rental, the death-rate is equal to 39 per 1000 of the population. The tenants in the large Canadian cities, adds Mr. Helbronner, are no better lodged. At Montreal, in the rich ward of St. Antoine, only 14·97 persons die per 1000, while in the workmen's quarters of Ste. Marie and St. Gabriel the mortality is 36·3 and 40·66 per 1000. In England the average life among the rich class is fifty-three years; it is forty-one years for the general population, and only twenty-nine years and a half for the labouring classes. Mr. Helbronner's report, if properly studied, will be found useful, and the Canadian Parliament has rendered a public service in causing it to be printed.

Archives de Physiologie de Dr. Brown-Séquard. No. 2, 1892. Paris: Masson.—This part contains no less than nineteen separate memoirs, of which the following are the more important:—1. M. A. Nicolas: Contribution to the Study of Gland Cells, especially dealing with those of the Lacrymal and Parotid Glands, with a Plate. 2. M. C. Phisalix: Physiological Researches on the Chromatophores of the Cephalopoda. 3. MM. Garnier and Voirin: On Alcaptonuria. 4. M. Laulanié: On the Relation between Thermogenesis and the Exchange of Gases in Respiration. 5. M. Hédon: On the Pathogeny of Diabetes consecutive upon Extirpation of the Pancreas. 6. M. Contrejean on the Gastric Juice and the Peptic Digestion of Albumen. 7. MM. Abelous and P. Langlois: Researches on the Functions of the Suprarenal Capsules. 8. M. Kaufmann: On the Circulation in Muscles in Action. 9. M. Prénant: On the Division of Cells, with a plate. 10. M. Gley: On the Function of the Thyroid Gland. 11. MM. Morat and Dufourt: Consumption of Sugar by the Muscles, and the Probable Origin of Muscle Glycogen. 12. M. Maurice Arthus: On Glycolysis in the Blood, and on the Glycolitic Ferment. 13. M. Girard: On the Formation of the Semicircular Canals of the Ear in the Frog. 14. Dr. Brown-Séquard: On the Localisation of Cerebral and especially of the Auditory Functions. 15. Sterilisation of Cold Liquids by Liquefied Carbonic Acid Gas, by M. d'Arsonval; and 16. Reflex Inhibition of Tonus and of the Gastric Movements.

Bacteriological Diagnosis: Tabular Aids for Use in Practical Work. By JAMES EISENBERG, Ph.D., M.D. Vienna. Translated and Augmented, with the permission of the Author, from the Second German Edition by NORVAL H. PIERCE, M.D., Surgeon to the Out-door Department of Michael Reese Hospital; Assistant to Surgical Clinic, College of Physicians and Surgeons, Chicago, Illinois. Philadelphia and London: The F. A. Davis Co., Publishers. 1892.—Dr. Pierce's translation of Eisenberg's "Bakteriologische Diagnostik" will be useful to those students of bacteriology who have no knowledge of German, as it appears to be both well arranged and well translated, though some of the terms used would sound rather strange to the ordinary English ear, especially the literal translation of such a term as "mycel," with the plural "mycels." For those, however, who can read German even moderately well, this work will be of little use, as, although the date of the imprint is 1892, the translation is made from Eisenberg's second edition—an exceedingly unfortunate circumstance, as a third edition appeared in 1891. From this latter edition the appendix on cultivation and staining methods has been added—an appendix that will prove of great value to laboratory workers. How far out of date the translation is may be gathered from the fact that all Eisenberg's preliminary tables have been omitted, and there are described in the translation only 138 species, whilst in the third German edition there are no fewer than 376 organisms included in the tables. The work is bound in oilcloth, a capital binding material for any book that is destined for consultation in the laboratory.

The Practical Guide to Algiers. By GEORGE W. HARRIS. Second Edition; Revised up to date and considerably Enlarged. London: George Philip and Son. 1892.—Making no pretence to the archæological lore, or the historic and ethnological research, which raises Murray's "Handbook of Algeria and Tunis" to a place of permanent authority in our libraries, Mr. Harris possesses knowledge enough of the region to act as a most serviceable guide to all who go as sojourners in search of the salubrious, the picturesque, and the generally interesting. No visitor to Algiers and the chief resorts in its neighbourhood need be at any loss in knowing his "way about" with the "Practical Guide" in his travelling bag; while, as to its excellence in regard to such far-famed watering-places as Hammam Meskoutine and Hamman R'hira, we can, from personal experience, pronounce a very favourable opinion. Mr. Harris prepares the reader for no more and no less than what he will find—thus obviating, on the one hand, all disappointment, if, on the other, preventing all chance of "agreeable surprise." The means of access, whether by coasting steamer, by railway, or by diligence; the hotels, under the several heads of accommodation, cuisine, and prices; the mineral waters; the features of interest from the artistic or historical point of view—all these, and many cognate details, are given by him with an accuracy that never creates false impressions, and with a fulness that satisfies without satiating. If we may venture a hint, we should advise him to enlarge his book in subsequent editions by dwelling more on the distant health resorts, like Biskra, called by Arabs the "Queen of the Desert," and remembered by grateful visitors as the seat of a "rest-cure" available when every place of sojourn on the Mediterranean is chill and cheerless. Biskra, indeed, is destined, before the century is out, to form the portal to the great "sun-bath of the Northern races," as the Sahara has been called—a sun-bath which is at its best when the Riviera and the Mediterranean seaboard generally are at their worst—rich, too, in verdant retreats provided by the neighbouring oases, which bring the "world's tired denizen" into immediate contact with the still life of patriarchal times, like so many pages out of Old Testament history. The good hotels of which it can now boast must, however, be made more accessible by rail—a consummation to which Mr. Harris can contribute by impressing on the unenterprising French directorate their neglected opportunities of reaping a golden harvest.

Analytical Records.

GASKIN'S COLONIAL COCOA.

(ANDERSON & COLTMAN, 155, FENCHURCH-STREET, E.C.)

COCOA when properly prepared is an excellent article of diet, and there are now in the market many good cocoas to select from. It is somewhat refreshing, therefore, to hear of a new claim made in respect to the above sample. Gaskin's cocoa is said to be made in British Guiana, where it is grown, and the advantage gained by this procedure is to secure a greatly improved flavour. The decoction it yields is characterised by a markedly rich and pleasant taste, and all excess of objectionable fat has evidently been carefully eliminated.

CELERY COFFEE.

(CELERY COFFEE COMPANY, 654, EGLINGTON-STREET, GLASGOW.)

Celery has been regarded by some as aphrodisiac as well as carminative, and it has a popular reputation of being a

Digitized by Google

cure for rheumatism. This latter reputed quality has doubtless prompted the preparation of the above article. In appearance and odour it is like ordinary coffee, though not so strongly aromatic, and yields a rich and not unpalatable infusion tasting like coffee, although the peculiar and pleasant flavour of celery can also be detected. Under the microscope scalariform vessels, which of course are highly characteristic of celery, may be readily observed. Celery coffee yields on ignition a bulky ash which contains carbonate of lime and an important quantity of soluble phosphate.

ESSENTIA MALTI KEPLER.

(MESSRS. BURROUGHS, WELLCOME, AND CO., SNOW-HILL BUILDINGS, E.C.)

According to our experiments, one part by weight of this preparation completely converts in one hour at 100° F. into dextrine and sugar no less than 8 parts of pure potato starch, and in two hours 16·66 parts. It is evidently, therefore, quite as active as regards diastase as well prepared extract of malt. In fact, the essence may be regarded more as a digestive agent than as a food, although it contains nearly 60 per cent. of solid malt-derived substances in addition to 0·65 per cent. of soluble phosphates. It is characterised by an agreeable flavour of malt, free from excessive sweetness, while from its fluid character it obviously presents certain advantages over the more viscous preparations. The fluid essence may be more conveniently used, for example, for mixing with aerated waters, plain water, or milk. With milk it forms not only a pleasant drink, but a valuable food.

MISCIBLE LIQUID EXTRACT OF COCA.

(WRIGHT, LAYMAN, AND UMNEY, SOUTHWARK.)

An abundance of cocaine was successfully extracted from this preparation, and the alkaloid was recognised by two tests—that of its numbing effect on the tongue and by the peculiar peppermint-like odour developed when the liberated alkaloid was evaporated to dryness with fuming nitric acid and afterwards moistened with a solution of potash in alcohol. The extract is not prepared by the addition of alkalies, but by a new process, which secures the elimination of useless chlorophyll and wax. It is a spirituous extract, and is marked by a strong, agreeable flavour. Moreover, it is perfectly miscible with water, and therefore admirably adapted for the extemporaneous preparation of coca wine and for admixture with malt extract or other suitable menstrua.

WYETH'S BEEF JUICE.

(JOHN WYETH AND BROTHER, PHILADELPHIA.)

The following analytical notes and results testify unmistakably to the excellence of this preparation. It is a dark reddish-brown liquid of pleasant beef-like flavour, and free from objectionable preservatives. It contains not only the albuminous principles of beef in an active and soluble from, but in the condition in which they occur in the freshly expressed juice of beef itself. Viewed with the spectroscope a dilute solution is seen to give two absorption bands, characteristic of fresh blood or hæmoglobin. The liquid loses this property, however, as soon as it is boiled; while the coagulated albuminous principles assume a blood-red tint. According to our experiments no less than fourteen grains of solid albuminous principles in every fluid ounce are thus precipitated. The following figures gained in analysis will convey some idea of the eminent degree of concentration through which this preparation has been carried. Notwithstanding this, the vital elements of beef juice it contains have been preserved unchanged. Moisture, 44·87 per cent; organic matter, 38·01 per cent.; mineral matter, 17·12 per cent. The organic materials contain 4·57 parts of nitrogen, and the mineral matter consists largely of common salt and, of course, soluble phosphate. Results like these make it safe to assert that as an example of preparations of this class Wyeth's beef juice is little short of perfection.

MALTO-RICINOL.

(KINGSFORD & CO., 54, PICCADILLY, S.W.)

It is well known that castor oil is one of the best of all simple purgatives, but its unpleasant taste is in many instances a drawback to its use. Like cod-liver oil, it appears to form an emulsion, as in the above excellent preparation, with active malt extract. The product so obtained is, according to microscopical examination, devoid of free fat globules, until water is added, when the preparation assumes at once a milky appearance. Malto-ricinol has an aromatic flavour, is not unpleasant to take, and contains besides half its weight of castor oil, all the valuable principles of active malt extract. It rapidly transforms starch jelly into soluble starch, and finally into dextrine and maltose. This preparation will doubtless prove a valuable addition to therapeutics.

GODESBERGER MINERAL WATER.

(THE GODESBERGER CO., 17 & 18, ST. DUNSTAN'S-HILL, E.C.)

A natural sparkling table water, peculiarly soft to the palate and free from organic matter. On evaporation a saline residue was obtained, amounting to 324 grains per gallon. Each bottleful, according to our tests, exhibits an alkalinity equal to 20 grains of bicarbonate of soda. The residue consists chiefly of carbonates of magnesia, lime, and soda, and sulphate of soda. The spectroscope showed also the presence of potassium. On account of its softness to the palate Godesberger water makes an excellent drink with milk, while, being practically free from iron, it mixes well with spirits.

MALT PASTILLES.

(ROWNTREE AND CO., YORK.)

Owing to the fact that the amylolytic activity of diastase is destroyed at a temperature exceeding 150° F., it has been found practically impossible hitherto to prepare sweetmeats containing active malt extract. Messrs. Rowntree have lately succeeded, however, in preparing malt pastilles in which the diastasic activity of the malt is really preserved. We have tried the action of the pastilles on starch, and find that they perceptibly dissolve and eventually convert the starch into dextrine and sugar. The pastilles have a pleasant taste, and, besides forming an elegant sweetmeat, may help to lighten the labour of digestion.

MOSQUERA'S BEEF MEAL AND JELLY.

(MOSQUERA JULIA FOOD CO., DETROIT, MICH., U.S.A., AND 16, COLEMAN-STREET, E.C.)

Two distinct preparations, beef jelly and beef meal, have been submitted to us by this firm. Both contain nourishing fibrine as well as peptone, the former being recognised under the microscope, and the latter by the well-known biuret reaction. Fat was also recognised. The meal on analysis gave the following results: Moisture, 8·60 per cent.; organic matter, 87·68 per cent.; mineral matter, 3·72 per cent.; and the jelly results as follows: Moisture, 22·10 per cent.; organic matter, 62·46 per cent.; ash, 15·44 per cent. The meal contained over 10 per cent. of nitrogen. In the face of these results it is evident that both preparations are foods particularly rich in restorative and nourishing elements. Further, they are of excellent flavour, and the entire absence of objectionable preservatives was ascertained.

THE Earl of Darnley on the 22nd inst. opened the new wing of the Kent County Ophthalmic Hospital. There was a large attendance at the ceremony.

THE LANCET.

LONDON: SATURDAY, APRIL 30, 1892.

BY the nomination of a new Royal Commission to take into consideration the means of forming a Teaching University for London another, and we hope a final, step has been taken. Just four years ago a Royal Commission was appointed to inquire "whether any and what kind of new University or powers is or are required for the advancement of higher education in London." This Commission was composed of Lord SELBORNE, Vice-Chancellor J. T. BALL, Sir JAMES HANNEN, the Hon. G. C. BRODRICK, Sir W. THOMSON, Sir G. G. STOKES, and the Rev. J. E. C. WELLDON. A more capable and judicious selection could scarcely have been made. The one blot in its composition was the absence of a thoroughly representative member of our profession who would have been able to assist in the solution of the medical difficulty which must be so inextricably mixed up with any scheme for improving higher education in London. The Hon. G. C. BRODRICK retired after the first meeting of the Commission. After hearing a large mass of evidence, and considering the petitions laid before them, the Commissioners reported to Her Majesty in April, 1889. They unanimously came to the conclusion "that a great demand exists for medical degrees attainable in London more easily than at present, and that it may be desirable to provide for that want in some proper manner," but they refused to grant a charter of incorporation to a Senate proposed to be formed of the Royal Colleges of Physicians and Surgeons, on the grounds that they were colleges of no academical character, and that the creation of a new examining and degree-giving University in a single faculty was undesirable. They also recommended that a reasonable time should be allowed to the Senate and Convocation of the University of London to consider whether they would apply to the QUEEN for a new charter extending their functions and duties to teaching; for, according to their opinion, the general case for a Teaching University was made out. The three practical teachers on the Commission would have preferred the establishment of a new Teaching University for London, but acquiesced in the recommendation that an attempt should be made to unite the teaching and examining functions in a single University. After numerous negotiations and conferences, the Senate formulated a scheme, and asked Convocation in June last to join in an application for a new charter, which was requisite for the carrying out of their proposed new functions; but by a very large and decisive majority the members of Convocation declined to do so. This was the first stage.

On the refusal of Convocation, the Privy Council took into consideration the question of granting a Charter to University and King's Colleges to form a University in and for the London district, with power to confer degrees, as prayed for in their petition which was presented to the QUEEN in Council at the same time as that of the Royal Colleges. Instead of remitting this subject to the Royal Commissioners, it was decided by the Lord President of the Privy Council to appoint a Committee of the Privy Council, composed of the Lord President, as chairman, and Lords SELBORNE, MONK BRETTON, BASING, and SANDFORD, to hear counsel in support of, and against, the petition. With the exception of that referring to the name, the objections of the University of London were disallowed, and the claim of the Royal Colleges to a control of the Medical Faculty in the new University was declared to be "not admissible." The medical schools of London were allowed time to consider whether they would take a part in the new University, and in July last agreed to do so. The charter of the Albert University, to be composed of University and King's Colleges and the London medical schools, was then passed by the Committee of the Privy Council. It was then too late for this charter to be laid on the table of the Houses of Parliament for thirty days as required by statute, but this was done immediately on the reassembling of Parliament in February last. Meanwhile, negotiations had taken place between the committee of Gresham College and the promoters of the new University which resulted in a welcome change of name from "Albert" to "Gresham." This constituted the second stage.

A new difficulty now arose. The provincial schools of medicine took alarm at the prospect of a new University for London which would have a strong Medical Faculty, and made strong pressure on their local parliamentary representatives to prevent the Charter being granted. They were joined in their opposition by members of the Convocation of the University of London, the authorities of Bedford College, and also by members of some other institutions, such as the Birkbeck Institution, the Working Men's College, the University Extension Society, and others, which did not appear before the Privy Council. This opposition proved so strong that the Government decided to reopen the question, and it has therefore been referred to another Royal Commission. This Commission was nominated on Monday last, and the terms of the reference are as follows: "We, taking the premisses into consideration, do authorise the said Commissioners to consider and, if they think fit, alter and amend, and extend the proposed Charter remitted in compliance with an address of the House of Commons, so as to form and report to us a scheme for the establishment under Charter of an efficient Teaching University for London." There is therefore no longer any question as to whether a Teaching University is needed; the matter the Commissioners have to consider is the formulating of a scheme for such a University by altering, amending, and extending the Gresham charter if they think fit. This is obviously a great advance upon the terms of the reference to the former Commission. The *personnel* of the Commission is altogether altered. No members of the former Commission are reappointed, and the selection appears to have been made on an entirely different plan. Instead of legal and educational authorities uninterested in the London problem, we have now a Commission composed of representatives of nearly all the bodies interested, and they are practically called together to agree on an efficient and workable scheme. Earl COWPER, the chairman, has no special interest in the question; Lord REAY is intimately connected with University College, and was the first chair-

Digitized by Google

man of the Association for Promoting a Teaching University; Bishop BARRY is a member of the Council of King's College, and was formerly its Principal; Sir LYON PLAYFAIR, as Member for South Leeds, and Vice-Chancellor RENDALL of the Victoria University, will safeguard the interests of the provincial colleges; Professor RAMSAY of Glasgow will represent the Scotch Universities; Professor SIDGWICK is one of the most active teachers in Cambridge; Canon BROWNE is a most ardent supporter of the University Extension system; Mr. JAMES ANSTIE is a member of the Senate of the University of London, and has had a considerable part in drawing up many of the schemes for reforming that University; and Mr. R. C. PALMER is a most influential member of the Gresham Committee and of the Mercers' Company. The members of the medical profession are Sir W. S. SAVORY, Sir G. M. HUMPHRY, and Professor BURDON-SANDERSON; but they practically represent the Royal Colleges and the medical schools of Cambridge and Oxford. Considering how seriously the interests of the medical schools of the metropolis are concerned, an active and representative London teacher should be added, and the Commission would have been still stronger if it had also included a general medical practitioner familiar with the advantages and defects attending London medical education under its present conditions.

THE term "tropical diarrhœa" is apt to be misleading; for although this condition has been investigated by the most able observers, yet it is by no means clear what is its pathology or morbid anatomy. Dr. THIN has done good service in this direction, especially with regard to the condition named by him "psilosis linguæ et intestini." In a paper recently read before the Royal Medical and Chirurgical Society, he has again drawn attention to the principal features of this complaint. Dr. THIN, following the doctrines of the Dutch physicians of Batavia, considers that psilosis, or, as it is commonly called, "sprue," is specifically distinct from the ordinary diarrhœa prevalent in the tropics. This distinction does not seem to be made in India or by French observers, whose statistics show that they group all cases of muco-enteritis into one class. Psilosis is characterised by a specific inflammation of the mucous membrane of the tongue, cheeks, soft palate, and œsophagus, superadded to the intestinal symptoms.

The condition of the tongue is especially characteristic, and may be apparent before the occurrence of diarrhœa. According to the severity of the symptoms the tongue may be slightly furred, with red, cracked, sensitive tip and edges, and very red patches on the dorsum, with enlarged papillæ. In a more advanced condition the tongue is free from fur, smooth, extremely red, with or without crevices, sometimes showing no trace of papillæ. When the patient is very anæmic the tongue may be pale and white towards the tip. The mucous membrane of the cheeks and lips may be pale and smooth or congested, the under lip and cheeks near the angles of the mouth being found sometimes extremely raw and tender, and covered with slight abrasions. In long-standing cases the remains of this inflammation may be present in the shape of an opaque thickening of the mucous membrane, which is liable to crack. In advanced stages slight superficial limited ulcerations occur on the mucous membrane of the cheeks as well as on the tongue. The extremely superficial character of the ulcerations is characteristic; they often vanish in a few days without leaving a trace. In a necropsy made by Dr. WETHERED on a case of psilosis, it was shown that the walls of the ileum were greatly thinned, the mucosa being completely denuded, contrasting very markedly with other forms of tropical diarrhœa in which the characteristic pathological changes were thickening of the walls of the intestines, and only partial destruction by ulceration of the mucous coat.

Another feature in these cases is of general interest—namely, the condition of the stools. Diarrhœa is indeed the rule, but it is not invariable. The condition of the bowels may be more accurately described as irregular. When diarrhœa does occur, the evacuations consist of a frothy, pale-yellow or clay-coloured, more or less pulpy, mass. When the motions become solid, the patient usually passes, once daily, a formed white colourless stool, and this colour is maintained, although the diet may consist of milk, farinaceous foods, fish, eggs, chicken, with a moderate amount of vegetables and fruit. Large creamy, soft masses are also passed occasionally, which have been shown to consist of almost pure cultivations of bacteria, a rod-shaped bacterium of moderate and definite size largely predominating over the other organisms present.

The fact of persistent white stools being passed when the patient is on a mixed diet raises the question whether colourless motions necessarily imply absence of bile. Dr. WALKER of Peterborough has shown that when the pancreatic duct is obstructed white stools result, and argues therefrom that the pancreatic secretion is a necessary ingredient of the colouring matters of the fæces. In the only necropsy of a case of psilosis which has been reported, the liver, pancreas, and their ducts were all normal. Dr. WYNTER BLYTH made an analysis of the stools of one of Dr. THIN'S patients, and showed that the general percentage composition was: water, 82·73; organic solids, 14; chemical matters, 3·27. More than half of the organic solids consisted of neutral fats, apparently milk fat, which had passed without being digested or saponified. Nearly 6 per cent. of bile acids were present as soap, thus showing that bile was not altogether wanting. As the fat in the stool was only a fraction of the quantity taken in the milk, it followed that a considerable proportion of the milk fat had been digested, thus affording clinical evidence of the presence of the pancreatic secretion. In fact, milk is the only diet that many of the patients affected with this disease can take.

The practical importance of these observations is obvious. It has generally been held that colourless stools denote serious interference with the functions of the liver or pancreas, either due to disease of the organs themselves or to obstruction of their ducts. We see, however, from the observations which we have just considered, that such is not necessarily the case; and it is a question well worthy of serious consideration whether in numerous other cases we are right in concluding that the liver and pancreas are not acting normally because this symptom (colourless stools) is present. Dr. THIN suggests that the colouring matter of the

Digitized by Google

fæces in psilosis is destroyed low down in the intestinal canal by bacterial action, and until some other agency has been discovered or this theory shown to be untenable we must conclude that the views hitherto held as regards the white stools, although probably correct in the majority of cases, are not complete, and that further investigation is necessary before the matter can be considered to be satisfactorily settled.

BRITISH gold used to form an essential factor in the war budgets of continental Powers, and history tells us how the aggressive policy of revolutionised France was kept in check by the subsidies doled out to Austria by the younger PITT. Nowadays no European State counts on such a source of supply in war time. "British gold" is otherwise and much more advantageously employed. And yet there are countries to which the inflow of that peculiarly precious metal is as indispensable as were PITT'S subventions to Austria—so indispensable, in fact, that a falling off in that source of revenue is felt as equivalent to a failure of crops or the exhaustion of an industry. Take Switzerland, for example. Is the tourist-wave from Great Britain kept back on some temporary account or deflected into another channel? A wail rises up from the cantons like the "bitter cry" from Lower Egypt when the fertilising Nile flood is over-due. Still more is this the case in Italy. Compared with her Swiss neighbour, the peninsula is much less developed in agricultural or industrial resource, and *pro tanto* her dependence on the fecundating tourist-wave is much more intimate. It is indeed a dire public calamity when for a season that wave refuses to flow through her Alpine passes or to caress her Mediterranean shores. Ten millions sterling we have heard Italian publicists mention as the sum annually spent among them by our compatriots, and if to that be added the seven millions estimated by American consuls in Italy as the contribution of their countrymen, and four millions as that of the Russian, the German, and the Frenchman, a total is arrived at of £21,000,000, computed in a recent paper by our first Secretary of Legation at Rome as the yearly amount poured into Italian pockets from the outside world.

The "human import" is indeed a source of revenue to Italy, before which her collective exports assume a comparatively humble figure; and the question now arises, What steps does she take to keep up so essential a factor of her income? The Swiss, we freely admit, show themselves alive to the value of the "human import"; they house him in model hotels; they feed him well; they maintain at his beck and call the best drilled army of waiters the world can show; above all, they are duly solicitous as to his health, and if they grudge him the power of calling in a practitioner of his own nationality, they do their best by first-rate sanitary arrangements to keep zymotic or preventable disease at a safe distance. And they have their reward in a fairly continuous inflow of tourists and in a yearly accession to their income, which, if it enriches the hotel-keeping beyond the professional citizen, has the compensating advantage of maintaining the general standard of comfort at an exceptionally high level. But Italy, owing far more than her Swiss neighbour to the foreign visitor, is far less careful as to his legitimate wants and claims. Her native hotels are still in many towns a byword—"thoroughly Italian" being the accepted definition in the guide-books for all that is mean in accommodation, insufficient in fare, defective in cleanliness, and risky as to hygiene. Could she but realise her opportunities she would regard it as a *prima cura* to make her guests—particularly her English-speaking guests—tolerably comfortable. They would then be attracted to regions of her beautiful and historically inviting peninsula which are practically closed to all but the adventurous and the robust. How many a delicious sun-trap on her Calabrian or Sicilian seaboard is still denied to the wistful valetudinarian from the north, on account of its squalid accommodation, its repulsive food, its defiance of the first principles of sanitation or common decency, its lack of all medical assistance, but that of some local SANGRADO? Even in the great centres of population—centres which successive generations of English-speaking residents have done something to civilise—the requirements of the British guest are but sparingly and grudgingly met. We say nothing as to the hotel system, which, when not in Swiss or German hands, is too often bad and dear; we mean the requisites which Italian citizens themselves should be the last to neglect—those of pure water-supply, prompt and effective drainage, removal of public latrines to quarters where they cease to assail every sense. This last is a crying evil in Italy, ay, even in such developed capitals as Rome and Florence. There the refined or properly-nurtured visitor, female even more than male, cannot thread the narrow lanes without incessant risk of having every propriety shocked by a worship of CLOACINA as promiscuous as it is unabashed. Public opinion has yet to be formed in Italy, and, when formed, to be exerted for the rehabilitation of manners and the observance of decency in out-of-door life. Other directions there are in which she has yet to improve upon semi-mediæval tradition, if she is to attract or retain her English-speaking guests. Her postal service, for instance, is of the poorest and most vexatious. Even abroad the Briton is alive to the value of time, and likes to have his letters punctually delivered or forwarded. But if the consensus of our countrymen even in such cities as Florence can be trusted, the posts are a daily source of worry and annoyance, neutralising much of the pleasure and benefit derivable from a sojourn in the beautiful city. Ill-advised economies in the service have undermanned it to the point at which efficiency is impossible, and mistakes in sorting and consignment are as irritating as they are frequent. Then, again, her custom-houses are the most exacting and provoking in Europe, and give the new arrival at her frontier anything but an appetising foretaste of the treatment in store for him when fairly within her gates. Italy has had warnings of the deterrent effect which her characteristic proceedings exert upon the visitor; and the ominous risk she lately ran of losing the advantages she draws from carrying our Indian mails by the Brindisi route convinced her, not a moment too soon, that she must improve her hôtel accommodation, moderate her custom-house pedantries, and put her public, including postal, services in order if she is not to see that lucrative line of traffic transferred to another Power.

Digitized by Google

The "human import," however, can connive at loss of comfort, at extortionate charges, at unlovely habits on the part of the natives, if only he can count on exemption from sanitary risks; and it is these which Italy still shows a reprehensible backwardness in removing. A few more lessons like those given her by the falling off in her "guest-friends" of late years, and she must find it imperative to put the prime requisites of health and life itself in the very front of her internal reforms. Had these been vouchsafed their due attention, no such falling off would have occurred; there would have been a substantial increase in the "import" in question; and the enriched country would have felt far less keenly the weight of her army and navy budgets, of her railway expenditure, of the cost of her colonial policy. It is not yet too late for her to retrieve her financial situation. But let her proceed properly to work. Not by economies here and imposts there, but by such sanitary rehabilitation as may do justice to her natural and historical attractions, will she recover the ground she is losing. And for that consummation let her draw her inspiring power not from statecraft merely, but from hygienic law befitting the country of BAGLIVI and MORGAGNI not less than of MACHIAVELLI and CAVOUR.

QUESTIONS of moral progress or retrogression are amongst the most interesting and important of all questions, and are constantly engaging attention, but the data for their scientific investigation are still scanty. Dr. ALBERT LEFFINGWELL has recently published a treatise,[1] which, he informs us, is the first work in the English language upon the subject with which it deals, although the question has attracted much attention upon the Continent. The materials for its elucidation, although still very imperfect, are rapidly accumulating, and Dr. LEFFINGWELL deserves the thanks of all scientific inquirers, social reformers, and politicians for the succinct and lucid manner in which he has marshalled his facts and drawn his conclusions.

The table of statistics of illegitimacy in Europe shows that Ireland stands at the head of the list with the lowest rate of all the European countries—viz, a rate of 26 illegitimate births in every 1000. This fact should be remembered to the eternal honour of the sister country. The English rate is 48 per 1000, and the Scotch no less than 82 per 1000. Thus we may roughly say that for every child born out of wedlock in Ireland two are born in England and three in Scotland. Looking again at the European table, we find that Ireland is closely followed in her place of honour by Russia, with the low rate of 28 per 1000, and by Holland with the rate of 32 per 1000. The Italian and French rates of illegitimacy are respectively 74 and 82 per 1000, being thus considerably in excess of England, and comparable rather to Scotland. Among the countries that show the highest proportion of illegitimacy are Sweden, Saxony, Bavaria, and Austria, in which the rates range from 100 to 140 per 1000. Austria is at the opposite pole from Ireland, and takes the lowest place among the European nations, with a rate of 146 per 1000.

[1] Social Science Series: Illegitimacy. By Dr. Albert Leffingwell. London: Swan Sonnenschein and Co.

When we study the detailed statistics of the British Islands many interesting and striking facts become apparent. We find the most marked differences in the illegitimate rate of the different counties and districts, and these differences are not arbitrary or fluctuating year by year but are remarkably constant, pointing to the operation of natural laws. As regards England, Dr. LEFFINGWELL points out that "if an outline map of England and Wales be taken, in which the county boundaries are distinguished, it will be found that a continuous, though irregular, line can be drawn from the east coast between Essex and Suffolk, across England to the British Channel; and that while every county below this line, without exception, has an illegitimate rate below the average, every county above it, with only one exception (viz., Lancashire), has a rate above the average." The extremes are shown by Essex, Middlesex, and Surrey, with rates respectively of 34, 35, and 40 per 1000, and Norfolk, Cumberland, Hereford, and Shropshire with rates respectively of 74, 76, 76, and 82 per 1000. Thus there are important districts in England where the rate of illegitimacy is almost as low as in Ireland; while in other districts it is almost as high as in Scotland. Turning to the latter country we find the same variations according to county and district. Ross and Cromarty, the Shetland Isles, Dumbarton, and Renfrew, at one end of the scale, have the comparatively moderate rates respectively of 47, 52, 54, and 59 per 1000; while Banff, Wigtown, Elgin, and Dumfries have the enormous rates of 164, 159, 153, and 147 per 1000. It is startling to find that these latter Scotch counties have actually one of the highest, if not the very highest, illegitimate rates in Europe. In Ireland, Mayo, Sligo, and Galway show the lowest rates—viz., 5, 8, and 10 per 1000; while the highest Irish rates are afforded by Antrim, Down, and Londonderry with 52, 51, and 46 per 1000 respectively.

The inquiry into the causes of these varying rates of illegitmacy raises many complicated but most interesting problems. Dr. LEFFINGWELL remarks that the causes generally supposed to be the principal factors in the production of vice and crime are poverty, ignorance, and the contamination of great cities. He examines the influence of these upon the prevalence of illegitimacy, and finds that it is very slight, if indeed it can be said to be operative at all. Thus, as regards poverty, we find astonishingly low rates of illegitimacy in poverty-stricken Mayo and Sligo, compared with the relatively high rates in prosperous Antrim and Down. It is also noteworthy that Russia, a very poor country, has a much lower rate of illegitimacy than such prosperous countries as France and England. Other facts too numerous to mention point in the same direction. Dr. LEFFINGWELL warns us, however, that "poor districts are not invariably the most virtuous," but adds that "there is nowhere such uniform relation between the indigence of a people and the prevalence of illegitimacy as to justify the hypothesis that this phase of moral delinquency in any district or country can be accurately described as caused by its poverty." As little can the influence of great cities account for the prevalence of illegitimacy. Thus the illegitimate rates of London, Birmingham, and Liverpool—viz., 39, 50, and 62 per 1000—are actually much lower than those of many of the purely rural districts. Education, again, seems to have

Digitized by Google

very little influence. Thus in the province of Finisterre in France, the most illiterate province in the country, the rate of illegitimacy is only 34 per 1000, as low as the lowest rate in any of the counties of England, Wales, or Scotland. Nowhere, unfortunately, can it be shown that the advance of education is marked by a relative decline in the rate of illegitimacy. Creed seems equally impotent to stem the tide of immorality. The low rates of illegitimacy in Catholic Ireland and Catholic Brittany are balanced by the high rates in Catholic Bavaria and Catholic Austria. Scotland and Sweden do little credit to Protestantism. We find the rates so variable under the same creed in different countries that to trace any causal connexion between belief and morals in this particular seems impossible.

We cannot at present adequately consider the real causes of the varying rates of illegitimacy. Race and heredity are apparently the most important, and next to these come legislation, restraints upon early marriages, social usage, &c. It is very satisfactory to find that on the whole the rate of illegitimacy in the various divisions of the United Kingdom is slowly declining. We may return to this subject, and in the meantime we commend Dr. LEFFINGWELL'S work to everyone interested in the study of morals and to all who are anxious to raise the investigation of these questions from the low level of sentiment to the higher plane of science.

Annotations.

"Ne quid nimis."

SIR GEORGE BUCHANAN AND THE LOCAL GOVERNMENT MEDICAL DEPARTMENT.

A VERY pleasant evening was spent at Limmer's Hotel on Saturday, April 23rd, when Sir George Buchanan entertained at dinner his late colleagues, the medical inspectors and clerks of the medical department, as well as the officials of the National Vaccine Establishment. After dinner the speeches were brief, but pointed and telling. The host introduced the new chief of the department, Dr. Thorne Thorne, in a few felicitous phrases, whilst the latter at somewhat greater length expatiated upon the severe loss they all experienced in Sir George Buchanan's retirement, and the eminent services he had rendered to the State in maintaining, as he had done, the prestige of the department. In reply, Sir George Buchanan claimed for Sir John Simon the lion's share in shaping the destinies of the inspectorate, to the direction of which he had succeeded; and he coupled the toast of "Absent Friends" with the names of Sir John Simon and Mr. W. H. Power, who was prevented attending from illness. Afterwards Dr. Blaxall, who has recently retired from the office of medical inspector, warmly welcomed the junior members of the staff to a service which he assured them would be one of which they would be proud in their after years. Altogether a most enjoyable gathering took place, which augurs well for Dr. Thorne's chieftainship.

THE ROYAL COMMISSION ON WATER-SUPPLY.

IT is satisfactory to learn that the members of the recently appointed Royal Commission on Water-supply mean to lose no time in starting their laborious task. A meeting was held on Monday last, when there were present Lord Balfour of Burleigh (chairman), Sir G. H. Bruce, Sir Archibald Geikie, Professor James Dewar, Mr. G. H. Hill, Mr. James Mansergh, and Mr. F. Gaskell, the secretary. The Commissioners had under further consideration several matters connected with procedure, and with the preparation of the maps and plans requisite for the inquiry; and they are believed to have expressed the hope that the preliminary statements for which the water companies and the principal public bodies interested in the inquiry have been asked will be in their hands before the close of the present month. If this should be the case, the Commissioners intend to proceed without delay to hear evidence, and will probably call first on the representatives of the existing water companies. Further, they have resolved to admit to the sittings at which evidence will be taken members and officials of any public body interested, as well as any official connected with any water company. Provision will also be made for the accommodation of a reasonable number of representatives of the press. No doubt many will gladly avail themselves of this opportunity of hearing evidence on a subject of paramount importance and of vital interest to the citizens of London.

CRUELTY TO CHILDREN ON THE CONTINENT.

WE may thank the framers of the Act for the prevention of cruelty to children that they have placed an effectual check upon those who in this country were wont to abuse the infirmities of children for begging purposes. The miserable show-infant cannot now be exposed in our streets without entailing serious risk upon the exhibitor in the event of detection. Anything like a wholesale manufacture of human objects of pity could not fail to draw down upon the perpetrators a penalty severe enough to prohibit its continuance. We have not, indeed, in this fact any occasion for boastfulness. Our assumption of preventive powers in the matter is far too recent even to encourage such an attitude. We cannot, however, be wrong in mentioning the circumstance by way of suggestion to authorities elsewhere who have still to witness, but apparently without power to punish, the monstrous practice in question. Take by way of illustration the frequent exhibition at French fairs of those artificially produced cripples known as *culs de jatte*, the term implying a shrivelled condition of both legs, deliberately induced in childhood by means of ligatures which interfere with the circulation in the limbs. The cripple-farmer pays the parents of his victim, usually a delicate child to begin with, a few centimes daily, and keeps his miserable charge as a means of lining his own pocket with the coppers of the compassionate. It is a proof of the extraordinary ignorance, credulity, and heartlessness of the Spanish peasantry, to whom these wretched creatures belong, that they should be allowed because born weak thus to suffer at the hands of impostors under the sorry pretence that only so can they make a living. It is evidently high time for preventive action on the part of the Spanish and French Governments, and no circumstance could provide a fuller justification for the introduction by either authority of a Children's Act which would deal effectively with instances of such tyrannous cruelty.

STREET CLEANSING.

A BRIEF *résumé* of observations on street cleansing contained in the recent report of Colonel Haywood, the engineer to the City of London Commission of Sewers, will serve to give some idea of the waste resulting from the ordinary wear and tear of City traffic. The report informs us that the number of persons entering the City on one day of last year was 1,186,000; that of vehicles, 92,000. We learn from it also that in order to maintain due cleanliness

Digitized by Google

all carriage-ways have to be swept daily, once at least. Some 150 boys are in constant employment as street orderlies. Many thoroughfares are cleansed by means of the water-hose, a total volume of about 3,500,000 gallons of water having been expended last year in the process. The cleansing of slums is a daily charge upon the authorities, and the total mass of refuse of all kinds removed during the year amounted, it is said, to 71,055 van-loads. Such facts as these will assist us in forming a judgment, however imperfect, respecting the properties of street dust. In view of their teaching, we can have no doubt as to the importance of securing effectual ventilation by the demolition of insanitary hovels and tenements, and the construction of wide thoroughfares. The work of daily cleansing becomes evident as a matter of mere necessity, and the water-cart or hose gains a new importance as a means of laying the pulverised refuse, laden as it must be with putrefying matter. The wisdom of vestries in using disinfectant solutions for this purpose during summer needs no commendation. Neither need we say much to impress the evident importance of maintaining in full working efficiency all street gullies, and of cleansing these frequently by means of antiseptic substances.

THE PROGRESS OF SMALL-POX.

SMALL POX continues to show indications of considerable activity in different parts of the country. A recrudescence has taken place at Dewsbury, cases recur at Batley, and odd cases are occurring at such places as Cleckheaton, North Bierley, &c. The result is a rush for isolation accommodation, and we fear that the erection of hospitals having been allowed to stand over until the disease has appeared, many structures which will be ill-adapted for anything but emergencies will be run up. One of the most serious attacks is at Great Yarmouth, where the hospital is full of small-pox patients. This is very ominous at a season of the year when further extension may be anticipated. Cases still occur in the metropolis, some being due to importation by Swiss waiters and other foreigners. Dr. Sykes of St. Pancras draws attention in his last monthly report to the fact, which he sets out in tabular form, that cases sent to hospital as small-pox are returned as being chicken-pox, although the houses and localities from which they were sent are infected with small-pox. We believe the Metropolitan Asylums Board are not allowed to isolate cases coming under the designation of chicken-pox.

THE SURGERY OF THE GALL-BLADDER.

DR. IVANOFF has collected the particulars of 278 cases of surgical interference with the gall-bladder on account of gall-stones or of distension from obstruction. Thirty cases were in males and 185 in females. The majority of them occurred in persons between the ages of forty and fifty years. In 64 cases the diagnosis was not made out, in 13 it was doubtful, and in 24 it was mistaken, being correct in the remaining 177. Of the 24 cases in which a mistake was made, in 7 movable kidney was diagnosed, in 6 hydatid of the liver, in 3 tumour of the omentum, in 1 ovarian tumour, in 1 cancer of the gall-bladder, in 1 cancer of the stomach, and in 1 acute peritonitis. There was a perceptible tumour of the region of the gall-bladder in 120 cases. An icteric colouration from obstruction of the flow of bile was present in 48 cases, in 30 of which it was persistent; in 10 of these last it was due to malignant disease of the parts which obstructed the passage. In the remaining 20 it was caused by obstruction of a gall-stone. In 40 cases there was an impacted stone found at the operation. Stones were found in some parts of the biliary passages at the operation in 140 instances. In one case there were 300 stones and in another as many as 1000. Empyema of the gall-bladder was found 16 times; adhesions to the abdominal walls and neighbouring organs occurred in 30 cases. The biliary passages were rendered impassable by contractions due to cicatrices in 5 cases, and by cancer affecting either the biliary system or organs in the immediate neighbourhood in 14 cases. There was icteric fever in 28 cases, independently of those in which the pyrexia was due to empyema of the gall-bladder; of these 28 cases, 10 proved fatal. Of the whole 278 cases, 36, or about 13 per cent., were fatal; 24 deaths followed normal cholecystotomy (i.e., the formation of an external biliary fistula), 6 followed cholecystectomy, 3 ideal cholecystotomy (i.e., the gall-bladder is sutured and returned into the abdominal cavity), and 3 followed cholecysto-enterotomy (i.e., the formation of a cysto-intestinal opening). The immediate causes of death were: in 9 cases collapse, in 1 uræmia, in 8 peritonitis, in 6 hæmorrhage, in 7 cancerous cachexia, in 7 pulmonary tuberculosis, in 1 pulmonary embolus, and in 3 cases the proximate cause of death could not be made out. The time taken by the artificial fistula to heal varied from five weeks to three years. Operative measures are, according to Dr. Ivanoff, indicated whenever there is great suffering, with more or less clear indication of obstruction of the bile-ducts. Normal cholecystotomy is generally the best and safest operation. When there is incurable impermeability of the bile-duct, the only effective operation is the performance of cholecysto-enterostomy.

ATHLETICS IN FRANCE.

WE are all familiar with the fact that, whatever qualities may be wanting in the French character, it clearly exhibits a perception—sometimes even too keen and too fearless—of logical sequences and of their practical issues. This national trait was illustrated, though in an eminently useful and rational degree, at the Physical Education Congress which recently met in Paris, and which, doubtless after due discussion, has left on record a series of creditable resolutions. These, if carried out, should at all events ensure the upturning of every available stone in order to rear the fabric of a sound physique. They make provision for the maintenance of a variety of forms of healthy recreation, from cycling to the juvenile matter—albeit no trifle in its own place—of ordinary school play. It cannot be said that any nation, not even France, has a monopoly in the practice of gymnastics, fencing, cycling, and the like; but it is something new to be confronted by competition from across the Channel when football is in question. Surely we had in this something like a British monopoly, and yet we find that a game played in Paris last week, though decided in favour of the visitors from our island, was closely contested. The omen is a good one, and suggestive of international comity under the best conditions. May it prove to be such; we for our part shall not grudge a form of rivalry which will go as far to ensure the mutual better acquaintance of neighbouring peoples as to promote their healthy physical development.

LEPROSY.

OUR contemporary the *Globe* publishes a brief notice of a report of the British consul at Riga, which deals with the prevalence and spread of leprosy in that city and its neighbourhood. It appears from the tone of this report that the usual dispute has been raging among medical practitioners at Riga as to the question whether leprosy is or is not spread contagion—or infection, as we should prefer to say. Of late in this district of Russia—as is, we incline to believe, also the case elsewhere, and out of Russia—the belief that leprosy is spread by virtue of its being an infectious disease is gaining much, and apparently rapidly, in both medical and popular opinion. Dr. Bergmann has, according to

Digitized by Google

this version of the consul's report, written a book which "effectually proves that the disease is spread by contagion." We quote from the statement in our contemporary of April 23rd, not from the consul's report, which we have not yet seen. Dr. Bergmann's book is, it appears, written with special reference to leprosy as it is seen in Riga and its neighbourhood, and his writings seem to have produced a considerable effect in favour of the "infectionists'" view of leprosy. The Riga authorities have, we are told, erected a leper asylum, with accommodation for forty patients—twenty men and twenty women,—besides rooms for bacteriological research in connexion with leprosy. There is, however, no power of compulsion vested in the Riga authorities when they have to deal with lepers. Hence there are only eighteen patients in the asylum, although "ninety-eight authenticated cases of leprosy are known to exist in the town alone ..... They [the lepers] continue to live at large exercising their daily occupation, and the disease is propagated." It may not be out of place (we believe it is very much *ad rem*) to remind our readers that this liberty of movement and perfect freedom to follow their various callings in life—e.g., salesmen in the bazaars—are precisely the conditions which obtain to-day in British India with regard to lepers. We conclude what we have to say for the present upon this most important subject by quoting a sentence from the notice in the *Globe* which is in the highest degree suggestive of many things. This is the sentence: "It is, however, difficult to discover the victims of this dire malady, as their relatives and friends hide them from the sanitary inspectors."

THE MEASLES BACILLUS

WE gladly draw attention to Dr. P. Murray Braidwood's letter published on another page. There is no doubt that the researches of our English workers are too frequently ignored, not only abroad, but at home. Dr. Ransome's observations on a measles bacillus, which were published some eight or nine years before Dr. Braidwood's paper was read before the Pathological Society, might claim priority were it not that in it, as in Dr. Braidwood's, no description of the organism or organisms as to size, structure, &c., sufficient to enable us to identify the organism is given. The work, exceeding good work for the time when it was done, was not accurate enough from the modern bacteriological point of view. The reaction of the bacillus to stains, then almost unknown, could not be determined, pure cultures could not be obtained, and the life history of the organism could not be studied. Any observations made at that time could only be purely tentative, and as the researches were never continued, and have been but little quoted in this country, it is perhaps little matter for wonder that workers abroad should have lost sight of them.

TREPHINING FOR EPILEPSY.

IN the *Boston Medical and Surgical Journal* Dr. Knapp records two cases of what he calls traumatic epilepsy, which were treated surgically by trephining. Every case of this nature, in the present state of cerebral surgery, is of the utmost importance, even if the result may not be all that is desired. The first case recorded is that of a girl who had an insane mother, and who, four years after an accident which rendered her unconscious for three days and necessitated a stay in hospital of several months, became subject to epileptic fits. In some slighter attacks she apparently did not lose consciousness, but the ordinary attacks commenced with turning of the head and eyes and culminated in general convulsion. She had a small stellate cicatrix on the forehead a little to the left of the median line at the spot where she had been struck with a stone five years previously. Underneath this was an area of rough, irregular bone with some depression. Bromides failed to relieve her, and operation was advised. The operation consisted in removing a circular piece of bone at the point where the cicatrix was, and excising a piece of thickened dura mater and some cicatricial tissue. The wound healed by first intention, but the patient had a convulsion about a fortnight after the operation, and the convulsions continued until she disappeared from observation. The second patient was a young man of eighteen, with nothing significant in his family history, who at the age of twelve had received a severe blow on the right temple. In less than a year he began to have seizures of various kinds—severe convulsions, slight lapses of consciousness, &c. Medicine did not relieve him, so far as it was tried, and he was trephined over the seat of injury. He also had a convulsion about a fortnight after the operation, and has continued to have them up till the present time. These cases are not very encouraging; but it must be borne in mind that, although the history of a head injury was clear enough in each, in one no fit had followed the injury until a year had elapsed, and in the other so long a period as four years intervened between the injury and the first convulsion. In the latter instance especially it is open to anyone to affirm, and with a fair amount of reason, that this was not a case of traumatic epilepsy strictly so-called, and this contention would receive support from the fact that the patient had an insane mother. The cases are by no means test cases; but, as we have already remarked, in the present condition of brain surgery every case of epilepsy operated upon is of the utmost importance, and should be recorded.

SIR GUYER HUNTER, M.P.

WE regret that among the many members who contemplate retiring from Parliament at the dissolution is Sir Guyer Hunter. Sir Guyer Hunter has been a very useful member, and has done a great deal of hard work in committees. He is among those who suffered severely from influenza, and who have still only imperfectly recovered from its effects. As a medical member of Parliament he will be much missed by all who know the difficulty of exciting attention in the House of Commons to questions affecting the health of the public or the interests of the medical profession.

YELLOW FEVER AT SANTOS.

THE reports as to yellow fever at Santos are very serious. Santos is the second commercial centre of Brazil, it being the only port to the rich province of San Paulo. It is situated on a low, marshy island, and contains some 20,000 inhabitants. The recent fatality from yellow fever is stated to have been really appalling; and this is largely attributed to certain works intended for the improvement of the port. For centuries the harbour has been made the receptacle for the filth of the town, besides receiving the refuse from vessels, and there being little or no tide, a thick deposit of filth has taken place. This stuff has recently been, and in all probability is still being, dredged up, and with a view of reclaiming certain portions of the foreshore it is being deposited there. The result is that a mass of feculent material, containing besides all sorts of organic refuse, lies exposed to the sun and contaminates the air around. And not only so, but the water of the harbour itself has become exceptionally foul by reason of the disturbance of the deposit, and it is under these circumstances that crews have been more than decimated by yellow fever. In connexion with a view that the emanations from the water itself are associated with the production of the disease, the *South American Journal* relates the following circumstance. Whilst in Santos the captain of one of the royal mail steamers gave strict orders

Digitized by Google

that the decks were not to be washed, but merely swept, and then sprinkled with a solution of carbolic acid. Not a single case of yellow fever occurred on this ship, though both the preceding and succeeding steamers which used the harbour water for washing down the decks were infected. On shore the disease has also made much havoc, and many of the inhabitants have fled from the place. Happily, with the advent of colder weather, the outbreak now gives distinct signs of abatement.

HYPERTRICHIASIS AND MENTAL DERANGEMENT.

DR. ANDREA CRISTANI has written a paper on this subject in the *Archivio di Psichiatria*, and an abstract of it appears in the *Neurologisches Centralblatt*. He has investigated 272 cases of insanity in females and a similar number of sane women with reference to the development of hair on various parts of the body, in which it is not found under ordinary circumstances. The insane ranged in age from twenty to eighty years, while the sane were all over sixty-five. He found that hypertrichiasis in the face as well as elsewhere is present much oftener amongst the insane than among the sane, that it is associated with signs of degeneration, and that it is more frequently present amongst insane patients in whom other signs of degeneration are present than amongst those who do not show degenerative symptoms. He also finds that the hairs are thicker and stiffer, and closely resemble those of the inferior races. The facts elicited are curious and interesting, and they are not easily explainable.

THE ORGANISATION OF VACCINATION IN FRANCE.

THE Comité Consultatif d'Hygiène Publique de France, sitting at the Ministry of the Interior under the presidency of Professor Brouardel, have issued the following statements with a view of securing the regular practice of vaccination by their fellow subjects. The rush for vaccination when the practice is allowed to stand over until small-pox appears leads to most unsatisfactory results, and it appears that the immediate cause of the issue of the statements which we quote has been the sudden demand for vaccination by 1000 people at Rheims—300 being brought for primary vaccination and 700 coming for revaccination:—1. Vaccination does not always preserve against small-pox. Experience has shown that after the lapse of some years a vaccinated individual can contract the disease. Commonly, in such a case, the small-pox is benign in character, but it no less contributes to propagate a formidable malady; hence the value of revaccination. 2. It is therefore a matter of general interest that individuals primarily vaccinated should be revaccinated after a lapse of time which experience has set down as ten years. Thus, a child of ten years old ought to be subjected to revaccination. 3. If this minor operation results in characteristic cicatrices, the individual is certainly protected against small-pox for a renewed period of ten years. 4. For this reason, so long as revaccination has not been successful, it is important to repeat the operation annually, and in case of an epidemic at even shorter intervals. So, also, it should be borne in mind that revaccination does not ensure protection for ten years except it has been practised with successful results. 5. Under these circumstances, revaccination, to give the utmost protection, should be repeated every ten years. 6. Revaccination does not of itself involve inconvience or suspension of work. 7. In brief, revaccination is a duty imposed on every good citizen. 8. To summarise: Vaccination is the most salutary of practices; it is also most harmless when surrounded by the precautions which in the present day have been clearly defined. It is, in reality, the only efficacious means for stamping out small-pox epidemics. The operation is so little painful, it takes so little time, and, since it involves no break of daily occupation, we are unable to understand why people hesitate to submit to it, in order to avoid a disease which is often fatal, which destroys eyesight, which deforms the features, and may result in active complications which are often incurable.

MEDICAL CORONERS.

WE have received a communication in which an objection is raised by a medical correspondent to medical coroners. He forwards us a newspaper report of an inquest held in Birmingham by Mr. Pemberton. That gentleman asked the medical practitioner, who was called to the deceased man when he was discovered dead, why he had not informed the coroner's officer of the death. Receiving an unsatisfactory answer, the coroner stated that it was the duty of everyone, including members of the medical profession, to inform the coroner of any sudden death, and that in future those doctors who failed to inform him of any such death to which they were called would not be called as medical witnesses, and that another practitioner would be called in their place. Our correspondent asks us "if this is our idea of medical coroners, and if we are aware that they are not usually kind to their professional brothers." We certainly fail to see any unkindness on the part of Mr. Pemberton in this case, and we must here remark that newspaper reports have the defect of not being able to report the tone in which coroners' remarks are made, or the expression of face with which they are accompanied. Many medical practitioners do inform the coroner of any death to which they are called; and as this, though involving very little trouble, is a great convenience to the coroner, it should be generally adopted, both as a duty and a courtesy to all coroners, whether medical or legal. Curiously enough, we have before us another letter in which medical coroners are objected to as being liable to screen their medical brethren when the latter are to blame. It is quite clear that Mr. Pemberton will not commit this error, and in thus acting he is only following in the footsteps of Mr. Wakley, Dr. Lankester, Dr. Hardwicke, Dr. Danford Thomas, and many other medical coroners who have shown that they can perform the judicial office of coroner with perfect impartiality to their medical brethren as well as to the public. Only last week we noticed that a legal coroner had appointed a doctor as his deputy. This, with the preceding facts and other cases which have recently occurred, are the best answers which can be given to those who doubt the perfect impartiality of medical coroners.

MULTIPLE NEURITIS.

IN an article in a recent number of the *International Medical Magazine* Dr. C. K. Mills of Philadelphia has published a clinical lecture dealing with this condition and its complications. The notes of several cases are given, some mild, some severe, one complicated with acute rheumatism, another with posterior sclerosis, and another with a cerebral lesion, causing apparently a slight condition of right hemiplegia. The descriptive account of each case is brief and to the point, but the chief interest of the paper lies in the few pages in which the subject of the treatment of such cases is considered. Dr. Mills insists upon absolute rest as a preliminary, and he emphasises the importance of gentle care in nursing patients suffering from neuritis on account of the excessive pain which handling and movement produce. He is not in favour of half measures in regard to the stoppage of the alcohol which is in most cases the toxic agent, and, except in the case of a few broken-down old topers, he thinks it should be withdrawn at once and

Digitized by Google

entirely, while the greatest care should be given to careful and abundant feeding. In a few sthenic cases he is inclined to advocate bloodletting, especially should there be any signs of congestion or inflammation of the spinal cord. For the relief of pain hot applications frequently renewed should be resorted to, and opium, best given hypodermically, may be necessary. As recuperative agents, strychnia by the mouth or hypodermically is recommended, as well as cinchona and digitalis; while such foods as milk and beef extracts will tend to have a similar effect. In the early stages salicylic acid or salicylate of soda, salol or oil of gualtheria, are recommended as anodynes which are especially useful if there is a rheumatic condition present; while cerebral symptoms are best counteracted by the bromides or antipyrine or acetanilide. Baths, simple or electrical, are also useful, but extreme care is necessary in giving them lest the patient should be in any way exposed to the danger—a very great one in those cases—of cold. Massage and passive or active movements can only do good when the stage of acuteness and excessive pain is passed, and the same is true of electricity in whatever form it may be found desirable to give it. The use of some anodyne ointment for massage is also recommended, but even with those numerous means of combating the condition, great patience and long-continued treatment are necessary if success is to be attained.

SCARLET FEVER AT THE FOUNDLING HOSPITAL.

FOLLOWING somewhat rapidly on the recent outbreak of enteric fever in the Foundling Hospital, there has occurred within the past three weeks a sudden outburst of scarlet fever amongst the inmates of the same institution. Its suddenness seemed to indicate milk as a vehicle of the disease; but whether this may turn out to be the case or not, it is the bounden duty of the governors no longer to delay making ample provision for the proper isolation of cases of infectious disease occurring within their walls. Dr. Sykes has strongly impressed this matter upon the governing body, and it is believed that they will use the utmost expedition in carrying out the necessary buildings.

THE LEGAL USE OF MEDICAL TITLES IN AUSTRALIA.

THE question of the legal use of medical titles is receiving the advantage of public discussion and the decision of the courts in Australia. Mr. Nicolson recently, in the District Court, fined a medical practitioner, one of the advertising fraternity, for two offences—first, for signing himself M.D. when he was not an M.D.; and secondly, for prefixing the title "Dr." to his name, he being registered only as a Member of the Royal College of Surgeons. Another case is that of a man calling himself "Dr. Singleton, oculist." He was convicted by the justices at Fitzroy for using the term "oculist." On the door-plate was "J. Singleton, oculist and aurist." Alfred Hardie stated that in going to the house he asked the defendant whether he was Dr. Singleton, oculist, to which the defendant replied, "Yes." The case was taken by way of appeal to the full court constituted by Mr. Justice Wood and Mr. Justice Williams. The defence was that the word "oculist" is not a medical or surgical name or title within the meaning of Section 11 of the Medical Act, 1890. The Court delivered the following judgment: "Now it lies upon the defendant in this case to establish that the conviction is wrong. We do not decide, or intend to decide, in this case that the term oculist may not be a name which is not a medical or surgical name or title within the meaning of Section 11 of the Medical Act, 1890. It is a term of double meaning. It may be such term or it may not be. But it appears from the evidence that there was evidence on which the magistrates could find that the defendant intended to use the term oculist on this occasion as being a medical or surgical name or title within the meaning of Section 11 of this Act, because when he was asked whether he was 'Dr. Singleton, the oculist,' he answered 'Yes.' Therefore, without deciding that this term oculist is, and must be, in all cases a term within the meaning of this particular section, we think there was evidence that the defendant intended to use the term in that sense, and therefore we think the magistrates were right, and the order will be discharged with costs." Mr. Duffy appeared to move the rule absolute. There was no appearance to show cause. These decisions have given rise to the usual controversy over the use of medical titles, and especially of the prefix "Dr." On the one side, it is strictly and jealously guarded as the right only of men with the degree of M.D. from the medical faculty of a University; on the other, it is treated as a trade-mark by which medical men are to be indiscriminately labeled. This controversy is perennial, and is not likely to be ended even by unmistakable legal decisions. There is, however, a growing tendency among medical men to respect their own titles and not to use those attaching to other qualifications. The public use of a prefix is not the question in dispute, but rather the legal and legitimate use of it in such a way as can be defended as a matter first of right and then of taste. To our thinking, the trade label theory of the prefix is an objectionable one. The whole question, however, is one of extreme difficulty. The public, as the result of some incomprehensible usage, choose to designate members of our profession under the generic description of "Doctor," a title properly appertaining to certain university degrees and by no means restricted to the Faculty of Medicine. If the universities had been content to employ the title of "Master," as is done in some cases, for their higher degrees, the difficulty would not have arisen; as matters stand, however, we cannot recommend self-respecting medical practitioners to lay claim to the prefix of "Doctor" unless it is theirs by right of a university degree as well as "the common consent of humanity."

EHRLICH'S TEST IN TYPHOID FEVER.

IT is now ten years ago since Ehrlich announced the discovery of a reaction that he claimed to be characteristic of the urine of typhoid fever. The value of the test, however, has been differently estimated by various writers. It was very soon shown that the reaction occurred in many acute diseases in addition to enteric fever, notably in measles and croupous pneumonia. It has undoubtedly a negative value; for if a reaction does not occur, the disease is in all probability not typhoid fever, although exceptions to this rule occasionally occur. Dr. A. R. Edwards of Chicago has made a large number of observations on this subject, and his results are published in the *Medical News* for April 2nd, 1892. One hundred and thirty cases of typhoid fever were examined. From two undoubted cases the reaction was absent throughout the disease, and the reaction was lacking in six in the period of defervescence. The test bears no relation to the ultimate issue, being equally brilliant in fatal and recovering cases. In sixty-three cases, in which the exact date of disappearance was noted, the average life of the test was thirteen days, although in some cases the reaction lingered until the forty-second and fiftieth days. Further, the reaction bore no direct ratio to the temperature. The general conclusions at which Dr. Edwards arrives are as follows:—1. The reaction is independent of any single disease or any group of diseases. 2. It is frequently found in urine containing albumen, peptone, biliary substances, sugar, aromatics, and possibly leucomaines or ptomaines. 3. Ehrlich's test is not always present in typhoid fever, even at the acme.

Digitized by Google

of the disease; it was absent in 1½ per cent. of the cases examined. The reaction, therefore, is at best only a presumptive, not a positive, evidence of typhoid fever. Its value is on a par with that of gurgling and tenderness in the right inguinal region, and inferior to the temperature, roseolæ, and splenic tumour. 4. Together with more reliable signs and symptoms, as temperature, enlarged spleen, &c., it may contribute to a diagnosis of typhoid fever, and conversely, when absent, in 98½ cases of 100, the disease is other than typhoid fever. 5. It is found in many other diseases, some of which, in certain clinical features, may simulate typhoid fever—e.g., septicæmia, uræmia, tuberculosis in its varied aspects, intestinal, peritoneal, miliary, &c., as well as enteritis, malaria, and pneumonia. In differential diagnosis, therefore, when other distinctive symptoms are lacking, the sulphanilic acid test is untrustworthy. It fails when most keenly wanted, and may be absent in otherwise typical cases of typhoid fever. 6 If much reliance is placed on the test, a typhoid fever relapse may be confounded with complications. Dr. Edwards observed as complications early sequelæ yielding the reaction, acute nephritis, lobar pneumonia, pulmonary tuberculosis, pleurisy, &c., and therefore he would have been at a loss as to the cause if confidence had been reposed in the test. 7. Inasmuch as it occurs typically in many diseases in which the causes and elaborated products differ, and since the various compounds with which the diazo-benzine sulphonic acid unites are as yet unknown, the reaction cannot commend itself to the scientific chemist, however it may be regarded clinically.

THE ROYAL COLLEGE OF SURGEONS.

THE Morton Lecture on Cancer and Cancerous Diseases will be given in the theatre of the Examination Hall, Victoria Embankment, by Dr. G. Sims Woodhead, on Thursday next, May 5th. Fellows and Members of the College are admitted, as to the other College lectures. Gentlemen who are not Fellows or Members can gain admission on presentation of their private visiting cards. The lecture will be delivered at 4 P.M.

SCHOOL WALKING TOURS

AMONG the various diversions of Easter we would note as of particular interest the new idea of holiday-making which was recently developed and applied in practice by the secretary of the Children's Country Holidays' Fund. This consisted in a walking tour in Kent and Sussex carried out by a contingent of forty boys from a Limehouse night school. Notwithstanding the cold and somewhat unsettled weather the excursion was completely successful in attaining its result in recreation without mishap to the members of the party or serious inconvenience to the country people who hospitably received them. A project of this kind, if well managed, possesses evident advantages over the ordinary stampede from town which occurs at each holiday season. It ensures the refreshment of country air for a certain period, of exercise without the necessity of overstrain and of a kind in which every limb and sinew is utilised, of mental change, in the direction of new scenes and places, which is in itself a means of education, and, lastly, it provides, at one stroke and economically, for the common happiness of many. We would not by any means repress or discountenance as objectionable the more customary attractions of the day out of town if order be reasonably considered, as happily it usually is. Still, it will be allowed that, after all, the swing-boat and the merry-go-round, with all their junketing accompaniments, the final train crush (of which we have just seen such an appalling example, as illustrated by the Hampstead catastrophe), and the weary home coming, can hardly promise the same wholesome result as the boys' pedestrian outing. Of course, like anything else, this will not suit every case. For able-bodied boys in their teens it has many advantages, and we therefore hope that, with due regard for special conditions of personal stamina, weather, clothes, housing, and the like, it will be often repeated in holiday times to come.

CHOLERA INTELLIGENCE.

CHOLERA is prevailing very extensively at Benares. Up to the end of last week there had been 180 cases and 130 deaths. A rumour has prevailed as to cholera in Paris; but the attacks were few in number, and even stated to be cases of cholera nostras only.

UNREGISTRABLE COLONIAL DEGREES

THE only colonial degrees and diplomas at present recognised and registrable under the Act of 1886 are those of Ceylon, New Zealand, Victoria, and New South Wales. On the 22nd inst. an inquest was held by Dr. Danford Thomas on a child, Thomas George McKerr, which had been attended by Dr. Thomas Joseph McDonald, living at Judd-street, Euston-road. On the death of the patient, Dr. Mcdonald declined to give a certificate, not being an English medical man. He stated that he held the degree of M.D. and C.M. of the University of Toronto; that he had bought a practice in Judd-street, to be carried on for him, till he could procure an English qualification, by Mr. Harrison, who had suddenly left him. Hence the difficulty and the necessity for an inquest. Dr. Thomas did rightly in advising Dr. McDonald not to continue practice under such conditions.

ENGLISH PORT SANITARY ADMINISTRATION.

THE sanitary committee of the Liverpool Corporation have lately been discussing the question of the mixed duty of Customs, Board of Trade, and sanitary officials in the matter of infectious disease on board ship within their port district. The subject was resumed at their last sitting, mainly because it is alleged that infection is constantly being conveyed into the city by means of passengers landed at the wharves. The sanitary committee are advised by Dr. Stopford Taylor that they do all they can to prevent this, but because the visiting officials of Government departments do not advise them of all cases of infectious diseases amongst passengers, emigrants, and others, infection is constantly introduced into Liverpool. And at the instigation of their medical officer of health, the corporation have addressed the Government urging a modification of the law so as to place all questions of quarantine, inspection of vessels, crews, emigrants, and others, under the single authority of the Local Government Board, instead of dividing it as hitherto between that body when cholera and ordinary port sanitary administration are concerned, the Board of Trade when it is a matter of emigrants, the Customs when cholera and quarantinable diseases such as plague are concerned, and lastly, the Privy Council Office, who alone administer the Quarantine Acts, but who are helpless to carry them out unless a vessel happens to sail straight into their one quarantine station at the Motherbank. The truth is that quarantine, as such, is a thing of the past for England, and hence the country has been lenient in allowing this absurd subdivision of duty to remain as an anomaly about which no one cared so long as quarantine was not carried out. But now that port sanitary authorities are determined to demand that they should not be turned into portals by which infection from any part of the globe may enter them, without their being so much as informed of the occurrence, it becomes clear that sooner or later the law must be altered. Our ports do not want to prohibit arrivals of infected people by sea any more than they do by

Digitized by Google

land, but they demand the notification of such cases so that they may adopt the necessary measures of protecting the public against injury.

BRIGADE SURGEON KENNETH McLEOD.

THIS officer retires from the service this month, and may shortly be expected in this country. We are glad to notice that the Senatus of the University of Aberdeen has conferred upon him the honorary degree of LL.D., and we cannot allow Dr. McLeod to retire without adding a few words of tribute to his long and admirable services in India. He is well known to be a man of great energy and culture, a capital surgeon, and in connexion with the Medical College Hospital and the Calcutta Medical College he has done much to advance the science of surgery and make for himself a well-merited reputation. Dr. McLeod is one of the many workers and men of distinction which the Indian Medical Service has produced. During his service in India he has filled many important posts, and the excellent character of his work has been generally recognised. He was the editor of the *Indian Medical Gazette*, and we need not remind our readers that he has contributed a good deal to medical literature. He founded the Calcutta Medical Society, and his departure from that city will, we feel sure, be a source of great regret to his friends, pupils, and patients.

COMPENSATORY HYPERTROPHY OF THE OVARY.

DR. ARISTOFF in his dissertation on the compensatory hypertrophy of the ovary, the materials for which he obtained from the pathological department of the St. Petersburg Medico-Chirurgical Academy under Professor Ivanovski, states that according to his observations when one ovary has been removed the other one increases in size and weight, the follicles coming more rapidly also to maturity and withering more quickly, besides which the medullary layer increases. In observations made on rabbits it was found that the hypertrophic process had begun within two months of the operation, and that at three or four months it had nearly doubled the size of the remaining ovary. After the fifth month the remaining ovary became smaller again.

SURGEON-CAPTAIN C. H. MELVILLE, M.B.

WE are glad to notice that attention has been called to the gallantry shown by Surgeon-Captain C. H. Melville, M.B., Army Medical Staff, during the late rising in North Lushai. This officer is serving in the Bengal Command according to the Army List. It is said that he displayed great bravery and coolness under very trying circumstances, and the occurrence affords another example of the gallant way in which medical officers behave when occasion requires.

VACCINATION IN THE WATFORD UNION.

ONE of the public vaccinators of the Watford Union has appealed to the guardians on account of the refusal of a parent attending his vaccination station to allow him to take lymph from the arm of a child who had been vaccinated by him. Oddly enough, the chairman urged upon the public vaccinator to be cautious, since reporters were present and the matter might get abroad. Why he did so is not very clear, for the guardians have a definite duty to see that the Vaccination Acts are carried out, and one section of the Act provides for the punishment of parents acting as this one did. People who come for gratuitous vaccination at public stations expect to find lymph available, and it would be absurd if the progress of the arm-to-arm work were to be stopped by reason of permission to take the lymph necessary to the maintenance of the station being refused. If the chairman had announced his intention to carry out the Act and to proceed against persons thus violating its requirements, the presence of the reporters could only have been helpful.

FOREIGN UNIVERSITY INTELLIGENCE.

Lemberg.—The local authorities have been authorised to spend 245,000 florins on a gynæcological clinic.

Prague.—Dr. Julius Pohl has been recognised as *privat-docent* in Pharmacology.

Vienna.—Dr. Dittrich has been officially permitted to become a *privat-docent* in Forensic Medicine.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Professor Franz Seitz, the Nestor of the Munich Medical Faculty, at the age of eighty.—Dr. Max Schrader, First Assistant in the Strassburg Medical Clinic, who is known by reason of his researches on the brain.

IN pursuance of an Act passed in the third year of the reign of His late Majesty, King William IV., intituled "An Act for regulating Schools of Anatomy," the Right Hon. Henry Matthews, Her Majesty's Principal Secretary of State for the Home Department, has appointed William Henry Bennett, Esq., F.R.C.S., to be an Inspector of Anatomy in England and Wales, in the room of Charles Hawkins, Esq., F.R.C.S., deceased.

WE understand that questions are likely to be put in the House of Commons to elicit from the Chancellor of the Exchequer a statement of the facts relative to the income-tax paid by medical men which will convey a more just impression of the case than the vague generalisations in his Budget speech.

WE are informed that the Home Secretary will shortly appoint a Committee to consider how best to deal with habitual drunkards, and specially to inquire into the working of the existing Inebriates Acts. We hope shortly to be able to announce the names of the Committee.

THE late Dr. Beaney of Melbourne has left the sum of £1000 in aid of the British Medical Benevolent Fund.

THE EXHIBITION OF THE ROYAL ACADEMY.

THERE may be less creative power in this exhibition than in some of its predecessors, but there is gratifying evidence of a more widely diffused artistic talent reaching a more uniformly excellent standard than in most we can call to mind. Proficient draughtsmanship and command of colour are of obviously more general attainment in the exhibitors, and their work is thus far less frequently impaired by *gaucheries* in execution or technical "causes of offence." But while it attests the higher special education, the more finished dexterity of the artist, it reveals him in all but a few cases deficient in ideal, conventional in inspiration, and conformingly *banal* in effect. He is still too much of the mere "reporter" of nature or of incident—too little of the poet, in fact, to interpret either of these in their nobler aspects. It would be invidious to give examples of what we miss in the majority of the works on view; let us rather indicate the direction in which genuine artistic power might make itself more distinctly felt than it seems—in many cases—to have given itself the chance of doing. Choice of theme is generally a sure test of that power; but how limited is the range within which the artist appears to interest himself t

Digitized by Google

We fear Thackeray's reproach is still relevant—there is a lack of reading, of mental cultivation in its higher sense, on the part of our painters and sculptors. The student of history could suggest an infinitude of subjects yet awaiting artistic interpretation and treatment if only he could be sure that his artist friend would do them justice. Let us venture on one or two—in sculpture first. Cicero discovering the tomb of Archimedes at Syracuse affords a really grand opportunity for plastic genius—the noble Roman standing from out the brambles and the brushwood, just cleared away, and looking down reverentially on the stone engraven with the insignia of the mighty engineer's calling—reverentially, but also with the proud consciousness that it was reserved for him, a man of Arpinum, to find out what Syracuse had not found to that day—the grave of her noblest citizen. And behind the dramatic situation, as rendered in the Tusculan Questions, there is its finely symbolical significance—the tribute paid by literature to science, which, but for literature, would often be without a voice and fade from the minds of men. Again, in the sphere of painting, what more striking theme could the artist select than Alexander the Great drinking off the potion in presence of the physician unjustly suspected of a design to poison him? The story is given with consummate power in the history of Q. Curtius Rufus—not the only one which appeals to the artist in that work,—but, in spite of its unique openings, has hitherto addressed itself to but the classical student. A yet more tempting subject for the painter is that prescribed for him by Puccinotti in his picturesque "Storia della Medicina"—young Harvey entering, arm-in-arm with Galileo, the anatomical theatre of Fabrizio Acquapendente just as that great teacher and investigator has been demonstrating the semi-lunar valves which Harvey himself was to utilise so effectively in establishing the circulation of the blood. Other themes, yet more susceptible of artistic treatment, would readily occur to the painter or sculptor if only he widened his mental horizon by that extended reading which Thackeray recommended for him. It would, however, be ungrateful to withhold from contemporary British art the debt we owe it. Creative in one sense, that art is recreative in another, rehabilitating the jaded faculties by the mental alterative, the moral eye-douche, so to speak, of ennobling scenes, of refining impressions, of inspiring sentiments, too often crushed out of sight or out of experience by the prose of daily circumstance. Refreshing to every sense, mental and physical, are such exquisite transcripts from nature as Peter Graham's "Sea-worn Rocks," or Henry Moore's "Perfect Weather for a Cruise," or MacWhirter's "June in the Austrian Tyrol," where "you scarce can see the grass for flowers." Sir J. E. Millais' "Halcyon Weather" is another of these, idealised by the true poet's touch; still more the same consummate artist's "The Little Speedwell's Darling Blue," as dainty a piece of presentation as heart could wish. Mr. Francis W. Loring's "Great Bridge at Chioggia, near Venice: Return of the Fisher Boats in the Evening," is a bit of Venetian colouring at once delicate and rich; and the praise of admirable finish in figure drawing and in colour is also due to Mr. Yeames' pictures from the Balearic Isles. The antique foretime re-lives for us in Sir F. Leighton's noble "Garden of the Hesperides" and Mr. Briton Rivière's "Dead Hector," for which the appropriate motto should have been—

Κεῖτο μέγας μεγαλωστὶ λελασμένος ἱπποσυνάων

and in Mr. F. Dicksee's "Startled," as lovely a pair of nymphs as ever fled before Horace's Faunus. The weird and sombre in art are powerfully rendered in Mr. Waterhouse's "Circe Poisoning the Sea"; in Mr. Johnston Inglis's "Idwal"—a mountain-side half veiled in ghostly mist and bathing its feet in a tarn as melancholy as a nocturne of Chopin; in Mr. Albert Goodwin's "City of Dis"—a powerful illustration of Dante's Inferno. Of purely medical subjects we remember but one, Mr. Dering Curtois's "Spring Afternoon: Johnson Ward, Lincoln County Hospital," where the contrast between the patients—one of them with the "facies Hippocratica"—and the reviving year without is touchingly rendered. We have but little space to indicate more than a sprinkling of the works that impressed us in our first walk through the exhibition; but we cannot close without a word of praise for Mr. Pettie's "Prince Charles Edward Stuart in the Cave of the Robbers of Glenmoriston," or Mr. Ernest Crofts' dramatic scene from the "Gunpowder Plot," or Mr. Val Princeps' "Broken Idol"—a powerful episode in the story of early Christian persecutions. In portraits, Mr. Herkomer and Mr. Ouless are equal to their best manner, and a word must be given to Mr. William Carter's speaking likenesses. Landscape we have already touched upon in Graham's and MacWhirter's work; but Mr. Ponsonby Staples' "Old Garden" deserves to be noted, as also Mr. Leader's Welsh scenes, and Mr. Chas. Stuart's "End of a Summer's Day," for their true sense of the lovely and the picturesque. In water-colours, Miss Mildred A. Butler's "High Court of Justice" is very clever in grouping and detail; while in sculpture the palm undoubtedly rests with Mr. Alfred Gilbert for his bust in bronze of Sir George Birdwood—a work of characteristic power and refinement. Other busts are not only interesting in themselves as works of art, but also for their subjects. Such are those of Dr. W. A. Guy, Dr. Lionel Beale, Dr. Weber, and the late Professor John Marshall.

SOME RECENT CONTRIBUTIONS TO OUR KNOWLEDGE OF THE PROCESSES OF BLOOD COAGULATION.

PROF. PEKELHARING'S name has of late been prominently before the scientific public in connexion with his important paper in Virchow's *Festschrift*. That paper consists for the most part of the setting forth of an ingenious hypothesis which is designed to bring facts which have long been known concerning fibrin ferment into harmony with the newer discoveries in connexion with blood coagulation. We have now two further papers from his pen, which contain some interesting facts bearing especially upon the researches of the late Dr. Wooldridge. The papers referred to are in the form of communications made to the Academy of Sciences at Amsterdam.[1] To appreciate these new-coming facts in their connexion with the old we may pass the history of the subject in rapid review. The advance in our knowledge with regard to blood coagulation has come in a series of waves. One of the great impulses to research into this question started from the discovery of fibrin ferment by Alexander Schmidt, and from the subsequent labours of his pupils upon the properties and the physiological importance of that substance. The results of Schmidt's work were briefly as follows:—He laid down that fibrin was formed by the union of a fibrinogenous and a fibrino-plastic element under the influence of fibrin-ferment, and he ascertained with something approaching to certainty that while the fibrinogenous element was contained in the plasma, the fibrino-plastic element was derived from the disintegration of white blood-corpuscles. Schmidt further identified the fibrinogenous element with the fibrinogen of the plasma, and he regarded para- (or serum-) globulin as the fibrino-plastic element.

Hammarsten now entered upon the investigation of the subject, and by improved methods succeeded in isolating plasma fibrinogen and paraglobulin, and in obtaining these substances in a condition of satisfactory purity. He then proceeded to investigate their relation to the processes of blood coagulation, and was able to demonstrate, first, that fibrinogen could be converted into fibrin under the influence of fibrin ferment quite independently of any addition of fibrino-plastic elements; and, secondly, that purified paraglobulin did not contribute any factor to the formation of fibrin. At the same time Hammarsten confirmed Schmidt to the extent that impure paraglobulin, such as could be precipitated from the serum, invariably increased the yield of fibrin obtained from a fibrinogen solution. The work of Schmidt and Hammarsten thus appears to have established the following propositions:—(*a*) The fibrinogen of the plasma is a mother substance of fibrin; (*b*) fibrin ferment has the power of inaugurating coagulation in fibrinogenous fluids; (*c*) there is in addition to the fibrinogen some other substance in the blood which contributes an element to the formation of fibrin; and (*d*) this fibrino-plastic element, whatever it may be, is certainly not paraglobulin. Fibrin ferment was in all these researches accredited with the *rôle* of presiding over and inaugurating coagulation, whether that coagulation was conceived of as a conversion of a

[1] Koninklijke Akademie van Wetenschappen te Amsterdam, Afdeeling Natuurkunde, Jan. 30th and April 2nd, 1892.

Digitized by Google

single mother substance (Hammarsten) or dual mother substances (Schmidt) into fibrin. As the presumptive first cause of all coagulation in extra-vascular plasma, fibrin ferment was now subjected to a number of searching trials with a view to eliciting its powers upon the intra-vascular plasma. The results of these experiments are well known. It was found that fibrin ferment did not cause any coagulation when it was injected into the vessels of the living body. What was held to be true in the case of the extra-vascular plasma therefore signally failed to establish itself as true with regard to the intra-vascular blood of the living body. Investigation had up to this point been following up an auriferous lode. It apparently came to a fault here. We find, therefore, that research branched off at this point into two different directions. Green[2] set himself to study what we may call the inorganic substratum of fibrin. He was the first who succeeded in clearly eliciting the importance of calcium in connexion with coagulation. The study was pursued by Ringer and Sainsbury,[3] and it culminated in the brilliant discovery of Arthus and Pagés[4] of the possibility of keeping the blood liquid by decalcification. The practical importance of these discoveries in connexion with the subject of transfusion and the arrest of hæmorrhage has been called attention to by Wright. At the same time that the importance of the calcium salts in coagulation was receiving the attention of investigators, Wooldridge in a characteristically brilliant way opened up a new field of research by his discovery of the effects of tissue fibrinogen on the blood. He found that the injection of this substance led to the occurrence of immediate intra-vascular coagulation, and he ascertained that the injected substance contributed a factor to the fibrin formed. Wooldridge also showed that where an injection of tissue fibrinogen was not followed by intra-vascular coagulation the blood lost its power of spontaneous coagulation. This loss of coagulability was described by Wooldridge as the "negative phase" of coagulability in contradistinction to the "positive phase" which was associated with increased coagulability and thrombosis.

Wright, who took up the question after Wooldridge's premature and lamented death, investigated the matter further. He showed that tissue fibrinogen was a nucleo-albumen,[5] and that the positive phase with its associated intra-vascular coagulation occurred only where the blood is supervenous.[6] He further showed that the injected nucleo-albumen became broken down in the blood into an albumose,[7] and that the phenomena of the negative phase were identical with the phenomena observed after albumose (peptone) injections. We have, further, on this subject the just-published researches of Pekelharing of Utrecht, which bring confirmation and expansion of these facts.

Pekelharing has discovered the presence of a nucleo-albumen in the plasma.[8] He surmises that it was originally derived from the white corpuscles which have disintegrated in the blood, and he finds that it is identical with the substance which Wooldridge obtained by cooling the plasma. He finds, further, that this nucleo-albumen, when injected into the blood, produces the same phenomena of a positive and a negative phase as those obtained after the injection of Wooldridge's tissue fibrinogen. He confirms[9] Wright as to the influence of a venous condition of the blood in favouring the intra-vascular coagulation, and quotes an experiment where he obtained, in lieu of coagulation, all the symptoms of peptone poisoning. This was in a dog, which was injected with tissue fibrinogen after thorough arterialisation of its blood by artificial respiration. Pekelharing goes a step further than Wright here; for, instead of only surmising the setting free of albumose in the blood from the symptoms, from the characters of the blood, and from its excretion in the urine, he obtains actual evidence (by Devoto's method) of presence of albumose in the blood of the negative phase after tissue-fibrinogen injections.

Lastly, Pekelharing takes essentially the same view as Wright[10] of the bearing of these matters on the theory of blood coagulation. The nucleo-albumen, whether obtained from the plasma by Pekelharing's method, or directly from the leucocytes, as in the preparation of Wooldridge's tissue fibrinogen, constitutes in the view of these observers the fibrino-plastic element which Schmidt asserted to be derived from the white corpuscles and erroneously assumed to be identical with paraglobulin. This nucleo-albumen, whether prepared from the plasma or leucocytes, has, from Pekelharing's account, solubilities which to some extent resemble those of paraglobulin. It is, for instance, entirely precipitated by $MgSO_4$, but only partially by saturation with NaCl. Probably it is identical with the substances originally described by Halliburton as cell globulins. We thus see that Pekelharing's researches appear to go some way towards reconciling certain of the diverging and apparently contradictory views which have been held on the subject of blood coagulation.

SANITARY APPLIANCES.

REPORT OF INTERNATIONAL JURY OF 1889.

French Drain Pipes.—Practical Experiments by the Jury of the Universal Exhibition held at Paris.

BY special favour we have been able to study the proof sheets of the report drawn up by the jury of Class 64 at the Universal Exhibition of 1889. This report was prepared a long time ago, and in some respects it is out of date, nevertheless it is not yet published. It is a Government report, and, like many other official documents, is hampered by so much red-tapeism that its publication has been delayed beyond all reason. Still, it is a very important report. Class 64 was devoted to hygiene, to public assistance or poor relief, and to mineral waters. This is the first time in France that a special class has been devoted to hygiene. It was formerly combined with and subordinated to medicine and public assistance. The progress of hygiene on the Continent has been, however, so great that it was converted into a class of its own situated close to Civil Engineering; and under the wing of Hygiene was placed Public Assistance, as if to show that the relief of the poor was a measure of public health. As mineral waters are an important and useful resource which nature offers for the prevention and treatment of disease, they were also put in the same category. The jury consisted of Drs. Brouardel, Proust, A. J. Martin, Th. Roussel, Napias, Le Mardeley, and Netter, all eminent French medical men. Then there were M. Bechman, chief engineer for the sanitary services of Paris; M. Henri Monod, chief to the Hygiene Department of the Ministry of the Interior; M. Nicholas, Councillor of State; M. Dislère, councillor and ex-director of the Colonial Department; M. Chérot, civil engineer and expert; M. Hudels, expert and demonstrator of physics at the Central School of Arts and Manufactures; M. Albert Lévy, chief of the Chemical Service at the Observatory of Montsouris; M. Louis Masson, expert and Chief Sanitary Inspector of Paris; and M. Mesureur, expert and President of the Syndical Chamber of Master Plumbers. There were but few foreign representatives on the jury. Still we note the names of Señor Palacios, Consul-General of Costa Rica, who was vice-president of the jury. Dr. Brouardel, dean of the Paris Faculty, was president, Dr. Proust, general inspector of the sanitary services of France, was the reporter of the jury, and Dr. A. J. Martin, secretary. Dr. Trinidad Pardos de Tavera represented Spain; Mr. Geo. F. Waring, jun., civil engineer, the United States; Dr. Faure Miller, Great Britain; and Dr. Reverdin, Belgium. Though the foreign element on this jury is undoubtedly weak, still it is impossible not to respect the verdict rendered by so highly distinguished and honourable a body of men. As we described at the time, the most elaborate and impartial experiments were made, and subsequently it was known which of the exhibitors had won medals. But what is more important, and what as yet has not been made public, are the exact nature and results of these experiments. In England especially is this knowledge needed, and it is regrettable that it has been withheld for so long. The fact is that England, first in the field and the leader in matters of practical hygiene, is now rapidly losing ground, and foreign manufacturers are beginning to make better drain pipes, better closets, better flushing apparatus, and better disinfecting stoves than those we place on the market. We take

Digitized by Google

it that the sooner this fact is known and understood the better.

There is, we think, no reason to be ashamed of such a result. On the contrary, to English sanitary reformers and to the manufacturers who have sought to apply in practice the principles these reformers taught, appertains the honour of having first solved the problems at issue. The English were the first to show how a closet should be built so that it might be absolutely inoffensive and self-cleansing. They also showed, notably during the Health Exhibition held in 1884 at South Kensington, how the merits of a closet could be tested by a jury. Now the French have at last realised the necessity of practical domestic hygiene, and they have quickly profited by the forty or fifty years' experience acquired in England. They have imitated nearly all our English models. In some cases the imitations are inferior to the original; but, in other instances, there are distinct improvements, particularly where nature, aiding, provides better clays than we have in England. Thus but a few years ago it was impossible to buy from a French manufacturer the wherewithal to construct a proper sanitary closet. English inhabitants and hotel-keepers catering for English patronage had to import from England the needful apparatus. Messrs. Doulton and Co., George Jennings, and others did a considerable business in France in the sale of closet pans, flush tanks, drain pipes, &c. French sanitary reformers readily recognise the debt of gratitude they owe more especially to Messrs. Doulton and Co., who have lavished large sums of money in making known throughout the French trade what constitutes a proper sanitary apparatus. It was the competition of these English manufacturers as much as the teachings of the professors of hygiene that finally induced the French manufacturers to mend their ways and adopt the new doctrines. Now the lesson has been so well conveyed, so thoroughly taught, that the pupils have in several instances outstripped their teachers. Not only is it easy to purchase in France from French manufacturers all the necessary sanitary apparatus, but in some respects these objects will be found superior to what can be obtained in England. Indeed, we have come to this, that unless English manufacturers bestir themselves we shall soon be importing drain pipes and other similar objects from France into England. Already thirty-three of our finest English mail steamers have a French disinfectant stove on board, as this apparatus is apparently superior to any of the kind offered for sale in England. The investigations of the jury demonstrate that, on the whole, better hardware drain pipes are made in France than in England. By experimental demonstration it was shown that some of the closet pans, the syphon traps, and the water waste preventing flush tanks, manufactured in France, are, to say the least of it, quite as good as those produced by the best English firms. Thus, in a very few years, we have not only been overtaken, but actually outstripped in the race for sanitary excellence.

On the other hand, this fact is so far of theoretical rather than of practical importance. The number of dwellings in France where these apparatus are in use is very limited. We know, for instance, that though in Paris there are more than 90,000 houses, barely 6000 out of this number can be considered as satisfactorily drained. Even in these cases shoddy wares have been introduced to a very large extent. It is an established fact in the trade that plumbers can purchase wholesale a waste preventer flush tank, a closet pan, and syphon trap, all complete, for the sum of 16s. Though at first closets thus cheaply bought seem to work well, they very soon get out of order, and thus wear very badly. This, however, is distinctly to the advantage of the plumber, who looks forward to being called in at an early date to effect the necessary repairs. This grievance is so widespread that the sanitary authorities are now promoting a Bill in Parliament by which it shall be illegal to employ sanitary apparatus in the construction of dwellings which have not been previously tested and approved by the municipal authorities of Paris. M. Louis Masson, the chief sanitary inspector of Paris, is now constructing a laboratory in which the test experiments will be made. But unfortunately a year at least, and perhaps two years, will elapse before the Bill becomes law and these experiments are rendered obligatory. In the meanwhile, a very large quantity of inferior wares will be manufactured and sold to the jerry builders of the French capital. We need hardly remark that similar defective closets are largely used in England, where a law on the same lines as that now submitted to the French Legislature would prove a great benefit in ensuring the satisfactory condition of our domestic drainage.

The experiments made by the International Jury are all the more valuable as the medals won by the exhibitors are no criterion whatsoever as to the merits of any one particular apparatus. The exhibitors were awarded medals for their exhibits as a whole, and the same exhibitor frequently displayed a very inferior apparatus by the side of another of exceptional excellence.

M. Louis Masson, chief sanitary inspector of Paris, M. Cherot, sanitary engineer, and M. Mesureur, deputy for Paris and president of the Syndical Chamber of Master Plumbers, were entrusted with the long and difficult experiments made to test the value of the closets exhibited. The first step taken was to measure and record the details of each pan. The distance from the rim of the pan to the level of the water within the pan was first noted. Then the amount of water retained in the syphon was ascertained and the depth of the dip forming the syphon carefully measured. These details having been obtained, each pan was submitted to a flush from identically the same flushing tank. These tanks gave a uniform discharge of ten litres, or a little more than two gallons of water at each flush. The pan was painted round with lamp-black, and careful note was taken as to how far the lamp-black was removed by the flush. The pan was now again painted a second time with the black, and small pieces of paper, uniform in number and in size, stuck upon the lamp-black. A second flush was given. Finally pieces of paper were floated in the trap, together with a certain number of potatoes measuring three centimetres in diameter, or wooden balls of the same size. A note was then taken as to the manner in which these various objects were cleared out of the syphon by the flush. The jury also examined how the pan and syphon were manufactured; whether the form was symmetrical, the materials good, the enamel sound, and, above all, whether at the joints between the pan and the syphon there was any roughness or risk of leakage. It was considered indispensable that the pan and the syphon should be of identically the same materials, and a porcelain or hardware pan affixed to an iron syphon would have been condemned. After completing these experiments, the jury reports: "Sanitary pans are now manufactured in France with as much success as in England. The French hardware and porcelain are as good, the shape of the pan is often better. The French potters have in a few years created manufactories of sanitary apparatus, and it is in part to their efforts that we owe the results which the jury has been happy to record. The pottery works of Rambervilliers, which were the first to make pans with syphons, and the pottery works of Pouilly-sur-Saône, whose exhibits were placed in an elegant pavilion, should be more particularly mentioned for their very excellent hardware, some of which was highly decorated, and looks almost as if it were porcelain. The society formed by the firm of Pillivuyt and the principal manufacturers of Paris exhibit objects that are excellent both in quality and in workmanship. The hardware of Mehun might be mistaken for porcelain."

The jury very energetically denounces the form of the seat of most closets manufactured in France; and we might add that this criticism applies equally well to the majority of English closets. The pan is generally placed within a sort of box, which reaches from wall to wall of the closet. In this obscure corner the workmen building the house throw any rubbish they are desirous of hiding. The box-like seat covers all this over. When the house is inhabited the rubbish under the closet seat gets wet whenever water is spilt or splashed, and thus, precisely at the spot where we need the most air, the most light, the greatest cleanliness, we have, in the dark and unventilated recesses that surround the pan of the closet, moist dirt and corruptible matter. The jury therefore strongly recommend the newer closets, where the pan is not covered over, and where the seat consists of a small piece of wood some four inches broad, that lifts up and down, to cover the rim of the pan.

In respect to the flush tanks, the jury did full justice to the first initiator and inventor of this style of apparatus, Mr. Rogers Field. They also congratulate the firm of Messrs. Doulton and Co. for being the first to introduce into France flush tanks of this description. They, however, now claim that the flush tanks manufactured by

Digitized by Google

Messrs. Geneste and Herscher possess all the practical qualities desired. These are, we need scarcely remark, simplicity in make and durability.

It is not necessary to follow the jury in their dissertations on the best methods of making syphon traps, on the dangers of syphonage, on the necessity of ventilating all pipes so as to prevent suction, on the need of openings into the syphon so as to clear away any obstruction that may occur. These are all questions with which plumbers who have been properly trained in sanitary plumbing are familiar. The point that is of interest is the fact that the doctrines so long preached by sanitary reformers in England formed the basis of the principles which the jury applied in testing the merits of the exhibits, and they found that several French manufacturers had attained this high standard of excellence. There is one feature in these foreign closets which should be carefully considered by those who in England build houses destined to be inhabited by a large number of poor people with dirty habits, and who use the closets in common. In that case it becomes a moot question as to whether it is wise to persist in providing seats for such closets. If the population of such dwellings is English, perhaps it would be better to persist in the English custom and trust to the influence of sanitary inspectors and others to bring about the required cleanliness. But where, as with the foreign Jews in Whitechapel or in the houses of Saffron-hill, inhabited exclusively by Italian organ-grinders and penny ice men, we have to deal with a foreign population, we must remember that the foreigner considers that the sitting down on a closet is at once a dangerous

TABLE I.—RESULTS OF EXPERIMENTS BY INTERNATIONAL JURY ON CLOSET PANS AND SYPHONS.

Name of the Exhibitor	Description of the Apparatus.	Distance between Edge of the Pan and Level of the Water in the Syphon.	Height of the Water in the Pan.	Syphon.		Effects of the Flush.		General Observations.
				Volume of Water retained in the Syphon.	Height of the Dip.	In the Pan.	In the Syphon.	
No. 1. — Usine de Rambervilliers.	Cuvette à plongée d'eau.	0·265 m.	—	0·0027 m.c.	0·05 m.	Good.	Good.	Good apparatus.
No. 40.—Rambervilliers.	Cuvette ovale de petite dimensions	0·225 m.	—	0·0012 m.c.	0·045 m.	Strong outside projection of water.	The papers were not cleared away.	Essay made with four litres of water. The pan must be rejected.
No. 5.—Messrs. Doulton & Co.	Oval porcelain pan (D²).	0·23 m.	—	0·0025 m.c.	0·052 m.	Good.	Good.	Good apparatus.
No. 6.—Messrs. Doulton & Co.	Oval porcelain pan (D¹).	0·265 m.	—	0·0023 m.c.	0·059 m.	Fairly good.	Incomplete.	Mediocre apparatus.
No. 20. — Jennings.	"The Pedestal" pan.	0·25 m.	0·025 m.	0·0012 m.c.	0·052 m.	Good.	Good.	Very good apparatus.
No. 13. — Jennings.	The "Osba" pan.	0·318 m.	—	0·0024 m.c.	0·043 m.	Insufficient.	Bad; wooden corks remained.	Apparatus to be rejected.
No. 29. — Pulliyuyt & Co.	"La Combinaison."	0·28 m.	0·02 m.	0·0012 m.c.	0·045 m.	Good.	Good.	Good apparatus.
No. 26.—Pulliyuyt & Co.	"La Chimère."	0·23 m.	—	0·002 m.c.	0·058 m.	Good.	Fairly good; one wooden cork remained after a second flush.	A bad copy of the Hellyer pan.
No. 34.—Pouilly-sur-Saône.	White round pan, syphon with narrowed entrance.	0·223 m.	—	0·0015 m.c.	0·02 m.	Flush sufficient, but some water thrown outside.	One wooden cork was not cleared out.	Fairly good apparatus, but the dip of syphon insufficient.
No. 33.—Pouilly-sur-Saône.	Cuvette à combinaison.	0·312 m.	0·017 m.	0·0015 m.	0·018 m.	Fairly good.	Bad; the papers and wooden corks were not cleared out.	Apparatus badly manufactured, though well studied in respect to form; dip of syphon insufficient. To be rejected.
No. 31.—Schellier & Co.	Round pan in porcelain; iron syphon.	0·26 m.	—	0·0025 m.c.	0·03 m.	Good.	Good.	Apparatus rather large, and requires a great deal of water.
No. 33.—Schellier & Co.	Round pan with syphon that can be applied to old closets.	0·233 m.	—	0·0026 m.c.	0·027 m.	Fairly good; some water thrown outside.	Flush defective; some papers remained.	Apparatus to be rejected.

TABLE II.—EXPERIMENTS OF THE INTERNATIONAL JURY ON THE ABSORPTION OF MOISTURE BY DRAIN PIPES.

Name of the Potteries.	Diameter.	Length.	Thickness.	Weight.		Quantity of water absorbed.	Observations.
				When dry.	After immersion in water.		
	Metres.	Metres.	Metres.	Kilogrammes.	Kilogrammes.		
Pouilly-sur-Saône ..	0·150	0·640	0·016	11,850	12,000	0·150	Immersed in water for 24 hours after being baked for 14 hours.
Ditto	0·100	0·650	0·013	7,300	7,700	0·400	Broken by 900 kilogrammes pressure.
Valabrègue	0·150	0·665	0·018	11,900	12,575	0·675	Immersion for 24 hours after 14 hours in oven.
Rambervilliers	0·150	0·665	0·018	14,200	14,350	0·150	Ditto.
Ditto	0·095	0·650	0·018	9,200	9,300	0·100	Crushed by 2400 kilogrammes pressure.
Muller	0·100	0·630	0·015	6,900	7,000	0·100	Crushed by 1000 kilogrammes pressure.
Ditto	0·150	0·655	0·020	13,800	14,800	1·000	Immersion of 24 hours after 14 hours in stove.
Noël	0·150	0·650	0·015	11,900	11,920	0·020	Crushed by an even pressure of 900 kilogrammes.
Ditto	0·100	0·630	0·016	8,100	8,200	0·100	Crushed by 1835 kilogrammes pressure.
Doulton	0·150	0·660	0·019	13,100	13,800	0·700	Crushed by a weight of 1200 kilogrammes evenly distributed.
Ditto	0·100	0·650	0·015	8,000	8,500	0·500	Crushed by a weight of 1600 kilogrammes.

Digitized by Google

and a dirty custom. There are also men of science who argue that the sitting posture is not in keeping with the anatomy of the human form. A number of French manufacturers exhibit closets the floor of which consists of fluted or seriated plate glass, the moisture running in the indentures of the glass; the feet have dry surfaces to tread upon. From the floor a small opening conveys by gravitation into the pan above the trap all liquids. The surroundings of the pan are of cement or hardware, the walls of enamelled tiles, and the window of thick glass with conical perforations. Thus every part of the closet is watertight and can be sluiced with buckets of water, while fresh air enters day and night through the perforated window panes. This form of closet is the best suited for people who do not take sufficient care in respect to cleanliness. The jury publish tables giving the results of all the experiments made. These are too numerous and too lengthy for us to reproduce, but we append some of the figures and facts relating to some of the best and some of the worst closets exhibited. These will serve as a specimen of the work accomplished by the jury. With equal care the jury tested the quality of the various drain-pipes exhibited. Those made of iron or of cement have been in use for many years in France; but Messrs. Doulton and Co. were the first to introduce hardware drain-pipes in France.

From Belgium and from Germany a smaller quantity of such pipes were also imported into France. But soon the French manufacturers began to organise for the production of goods of this description, and many specimens of this new French industry were sent to the Exhibition. Each pipe was submitted by the jury to four different test experiments. First, it was placed under a lever. A weight attached to this lever was pushed gradually towards the end of the lever, thus increasing the pressure on the pipe at each forward movement. The lever was practically a scale, and it was thus easy to ascertain how many pounds pressure was required to break the pipe. The second experiment had for purpose the testing of the force required to burst the pipe by inside pressure. The pipe was placed vertically on a table, the two extremities hermetically closed by heavy metallic planks with indiarubber flange. Each metal covering had a hole in the centre. From the hole on the top water was poured in till the pipe was filled. The hole was then closed with a screw nut. From the hole below a pipe communicated with a hydraulic press, by means of which internal pressure was gradually produced till the pipe burst. A manometer fixed on a branch tube recorded the amount of pressure brought to bear. The third experiment consisted of testing how far the pipes could resist the shock of a blow. For this purpose a metallic sphere weighing nine kilogrammes was allowed to fall from various measured heights on to the centre and upper portion of the pipe. The pipe was laid on a wooden groove, so contrived as to disengage the socket of the pipe, so that its protuberance should not effect the fragility of the pipe. The fourth experiment was conceived with the view of ascertaining how far the drain-pipes absorb the water which passes through them. Each pipe was placed in the portable stove supplied for baking the bread of the French army. The pipes remained for twelve hours in this stove, and might therefore be considered as perfectly dry. They were then immersed for twenty-four hours in water. Each pipe was carefully weighed before and after this immersion, and the increase in weight after the operation showed to what extent water had been absorbed.

The result of all these experiments was, it must at once be confessed, not satisfactory so far as the English exhibitors were concerned. It was in respect to the pervious nature of the hardware that the English goods were most at fault. The jury made a calculation so as to ascertain the coefficient of each exhibitor. The maximum number of marks attainable was 1300. The Mousen Pottery Works obtained 970 as their co-efficient, the Rambervilliers 960, the Pouilly-sur-Saône 920, Messrs. Doulton 860, and the Muller Potteries 830. It was in respect to the porous character of the materials employed that the last two failed to come up to the mark. Thus we find that they obtained no marks whatsoever in respect to permeability, whereas the firms of Mousen and Rambervilliers obtained each 300 marks, and Pouilly 260. On the other hand, when tested for their power of resisting shocks or blows, the drain-pipes of the Mousen potteries received no marks at all, and the Rambervilliers and the Pouilly potteries obtained but 100 marks each, while the Muller potteries obtained 300 marks, and the Doulton potteries were at the head of the list with 320. The fact of the case seems to be that the clays found in France are better suited for the manufacture of pipes of an impervious nature.

We cannot reproduce in detail all these experiments, but give some specimens. With regard to the closets, we reproduce from the report of the jury the best and the worst specimen exhibited by six of the best makers. The other exhibits fell below the mark of what is here recorded. (See Table I.).

With respect to the drain pipes, it would take too much space to give the measurements of each pipe tested and the results acquired, but here, for instance, are a few figures taken from the extremes of good and bad. The pipes of the Rambervillier's potteries were crushed by weights amounting for the best specimens to 2500 kilogrammes and 2200 kilogrammes, for the worst to 1100 and 1200 kilogrammes. For the Muller potteries the extremes were 1850 kilogrammes the best; 1000 the worst. For Pouilly-sur-Saône, 1350 kilogrammes, the best; 800 kilogrammes the worst. For the Valabrègue works, 1800 kilogrammes the best; 600 kilogrammes the worst. For the Haine St. Pierre works in Belgium, 2450 kilogrammes the best; 900 kilogrammes the worst. For the Boussieux works in Belgium, 2050 kilogrammes the best; 800 kilogrammes the worst. The other trials show an almost equal difference of merit, but it is the coefficients rather than actual results that are instructive, and these we have already given. With the hydraulic press the rupture from internal pressure, varies for the Pouilly-sur-Saône pipes, from 4 kilogrammes to 11 kilogrammes. For the Rambervilliers pipes, from 1·5 kilogramme to 10·5 kilogrammes. For the Doulton pipes, from 4 kilogrammes to 10 kilogrammes. For the Haine St. Pierre Belgian pipes, from 6 kilogrammes to 18 kilogrammes, and from the Valabrègue, from 3·5 kilogrammes to 4 kilogrammes. Then in conclusion we have the results of the experiments made to test the absorption of moisture by hardware drain pipes given by the jury. (See Table II.).

THE INTERNATIONAL CONGRESS OF THE RED CROSS.

AN Italian correspondent writes:—The historic *Sala degli Orazi e Curiazi* (Hall of the Horatii and Curiatii) in the Palazzo dei Conservatori, in the Capitol, was on Thursday, the 21st inst., the scene of a brilliant assembly—that of the Fifth International Congress of the Red Cross. Of the 172 delegates, Italian and foreign, invited to take part in the proceedings, all but a very few were in attendance. The majority wore on their breasts the insignia of the knightly orders to which they belong, and the foreign delegates were grouped according to their respective nationalities, each group being indicated by a reduced copy of its national flag. At the dais, on which the President (the Senator della Somaglia) was seated, there figured among the artistic decorations a large red cross bearing the rubric "Ginevra, 22 Agosto, 1864" (Geneva, 22nd August, 1864)—the date of the foundation of the International Society. Supported by General Cosenz, by the distinguished statesmen, Signors Pelloux (War Minister) and d'Arco, representing the Government, and by the Prefect and Syndic of Rome, Count della Somaglia opened the Congress in French, summarising the history of the philanthropic movement, its steady development, and the benefits it had already conferred on humanity. Having touched on the programme of this, the fifth, Congress, he read a communication from the Secretary-General of the Ministry of the Royal Household. The following are its terms:—

"Their Majesties the King and Queen of Italy, desirous of attesting their high appreciation and approval of the Fifth International Congress of the Association of the Red Cross, which takes place in Rome, have resolved to open a competition resulting in prizes for the best contributions to the cause which the philanthropic institution has at heart. The august sovereigns, convinced that promptitude in aiding the wounded is the most effective factor in the happy issue of their tendance, have determined that the subject of the present congress shall be exclusively the perfecting of the means for the immediate clearance

Digitized by Google

(*sgombero*) of the battle-field, by the transport of the wounded to the relief-stations, from these to the advanced posts of medico-surgical treatment, and finally, from these to the places of first temporary hospital accommodation. With this view, their Majesties have placed at the disposal of the President of the Congress the sum of 10,000 Italian lire (£400) to be divided into two prizes, besides acts of honourable mention embodied in silver medals bearing their Majesties' likeness, which will be provided by the Ministry of the Royal Household. The competition will be international, and will be held in Rome, where it will remain open till the end of June, 1893. Their Majesties leave it to the Congress to establish the details of the conditions of the programme and the other formalities connected with the competition. The august sovereigns are earnest in their wish that the happy issue of the competition may conduce to the furtherance of those philanthropic endeavours undertaken by the Congress, whose proceedings they will watch with lively interest as additional proof of the glorious conquests already won in the field of civilisation and human brotherhood."

Loud applause ensued on this characteristically generous and enlightened action of the House of Savoy, after which the Count della Somaglia, concluding his address, made use of these words: "Let me therefore express the hope which is in the hearts of one and all of us that this sentiment may become so developed among peoples and Governments as to restrain them from the resort to arms, and that there may finally descend on the world an aureole, the messenger of concord, to unite the nations in one sole thought, the ideal of peace, of fraternity, of progress." Signor Pelloux, speaking in the name of the Italian Government, echoed the Royal and Presidential hopes, and, representing his colleagues, welcomed the members of the Congress to their labours in Rome. He dwelt on the mighty services already done by the Red Cross in war, services it is capable of doing on a yet greater scale, first among which will be the solution of those means of prompt transport of the wounded from the battle-field which the Congress has more particularly undertaken. The Syndic (the Duke of Sermoneta) extended the right hand of fellowship, on the part of Rome, to the foreign delegates, and dwelt on the fond anticipation of seeing the Red Cross, by enlarging its functions, bring about peace and goodwill among all men. This anticipation, or rather hope, he liked to associate with the august day of their meeting—the 21st of April—the birthday of the city of Rome.

Dr. von Coler, of the medical staff of the German War Office, referred also to the coincidence of the meeting of the Conference with the 530th *lustrum* of Rome's foundation—a meeting convened under the auspices of a Royal house which by its universally acknowledged philanthropy had won the respect and admiration of the world. "The Emperor of Germany," he added, "always inspired by true sentiments of charity, had expressed to him the wish that everything that can conduce to the better tendance and relief of the wounded should constitute no secret, but become the common patrimony of all the nations of mankind." Dr. von Coler further indicated the noble charities of the Empress Augusta and the Empress Victoria as showing that the Geneva Convention had won the heart of Germany, in the name of whose sovereigns and people he concluded by a cordial greeting to the members of the Congress.

Business thereafter commenced.

A discussion started on the following order of the day, that "the Fifth Congress expresses the desire that the signatory powers of the Geneva Convention should unite to extend the benefits of the said Convention to maritime warfare under the conditions and in the degree applicable to the said warfare," elicited some difference of opinion as to the rights of belligerents which might possibly be compromised by the action of the Red Cross. An alternative order of the day was outvoted and the original one adhered to. Next came the report of the committee on the prompt transport of the wounded from the battle-field, according to which it appeared that there is a common effort now in progress among the military authorities of all civilised countries to promote facilities for that most desirable object. Questions, however, have yet to be solved before a practical *modus operandi* can be set on foot—questions relating to the risk incurred by the *personnel* of the Red Cross in removing the wounded under fire. Herr Criegern (from Saxony) urged the necessity of having the places for receiving the wounded as near the scene of action as possible, the preference being given to the more severely wounded. Stretchers specially made *ad hoc*, and special cars, all under the management of military companies told off by the War Office authorities for the purpose, and assisted, if need be, by volunteers, were among his recommendations. Further, the Powers in time of peace should have prepared, against the outbreak of war, a sufficient supply of mattresses and beds, and an organisation for serving to the wounded in action such cordials or restoratives as they may require when lifted from the ground and during their transport. An order of the day embodying Herr Criegern's proposals, and referring them to the Central Committees of the Red Cross, was carried.

Dr. Gurlt, Professor of Surgery in the Berlin School, was the most prominent speaker on another branch of the subject—the improvement of means of transport for the wounded. He strongly recommended those on the von Döcker system as having hitherto given the best results. Professor Postemski, of the Roman University, urged that the question, as a medico-technical one, was beyond the sphere of the Congress to discuss, and proposed its being left to each country to choose its own system—a proposal which was eventually carried.

M. de Hardenbrock (from the Netherlands) proposed: first, that in distant wars, or in wars beyond sea, the Red Cross societies whose service is invoked should place themselves *en rapport* with the military authorities and the army medical staff of the belligerents through the medium of the Red Cross societies belonging to those belligerents, or through diplomatic intervention; secondly, that in wars between signatory powers and others the society whose assistance will be invoked should have the right, as a primary condition, to demand that the Power which has not adhered to the Convention should be compelled to conform to its provisions. The Marchese Vitelleschi found this a very important question, and proposed its being referred to a special commission. After various arguments, in which France and Russia were represented, the Marchese Vitelleschi's proposal was approved.

The discussions were relieved by a visit to the Monte Celio, where the "Treno-Lazaretto-Tartaruga" was exhibited. It consists of four waggons with sixty beds, and is provided with every requisite for a field hospital, which may occupy a fixed position for as many days as may be necessary, while, in case of need, it can be moved to any distance with the maximum of swiftness and the minimum of vibration or discomfort to the wounded inmates. It evoked universal admiration as a great and effective improvement on the movable tent system found so useful in African warfare.

(To be concluded.)

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6272 births and 4253 deaths were registered during the week ending April 23rd. The annual rate of mortality in these towns, which had been 23·3 and 20·9 per 1000 in the preceding two weeks, rose again last week to 21·8. In London the rate was 21·0 per 1000, while it averaged 22·3 in the thirty-two provincial towns. The lowest rates in these towns were 13·9 in Brighton, 14·9 in West Ham, 15·7 in Croydon, and 15·8 in Plymouth; the highest rates were 25·8 in Manchester, 26·2 in Wolverhampton, 28·0 in Salford, and 28·3 in Derby and in Bolton. The 4253 deaths included 541 which were referred to the principal zymotic diseases, against numbers increasing from 427 to 495 in the preceding three weeks; of these, 197 resulted from measles, 172 from whooping-cough, 58 from diarrhœa, 46 from diphtheria, 44 from scarlet fever, 20 from "fever" (principally enteric), and 4 from small-pox. No fatal case of any of these diseases occurred last week in Plymouth; in the other towns they caused the lowest rates in Brighton, Croydon, Halifax, and Nottingham, and the highest rates in Sunderland, Salford, Sheffield, and Bolton. The greatest mortality from measles occurred in Birmingham, Sheffield, London, Liverpool, Sunderland, and Leicester; scarlet fever in Cardiff and Gateshead; whooping-cough in Burnley,

Digitized by Google

Blackburn, Wolverhampton, Preston, Sunderland, Salford, and Bolton; and diarrhœa in Salford. The mortality from "fever" showed no marked excess in any of the thirty-three large towns. The 46 deaths from diphtheria included 29 in London, 5 in Sheffield, 3 in Newcastle-upon-Tyne, and 2 in Manchester. Two fatal cases of small-pox were registered in London, one in Oldham, one in Leeds, but not one in any other of the thirty-three towns; 48 cases of this disease were under treatment in the Metropolitan Asylum Hospitals, and 10 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1400, against 1289 and 1296 on the preceding two Saturdays; 219 new cases were admitted during the week, against 166 and 146 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 523 to 348 in the preceding five weeks, rose again to 389 last week, and almost corresponded with the corrected average. The causes of 103, or 2·4 per cent., of the deaths in the thirty-three towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Croydon, Portsmouth, Norwich, Birkenhead, and in four other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Preston, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 24·1 and 22·5 per 1000 in the preceding two weeks, declined again to 22·3 during the week ending April 23rd, but was 0·5 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·7 in Perth and 15·1 in Aberdeen to 24·8 in Greenock and 26·0 in Glasgow. The 622 deaths in these towns included 22 which were referred to whooping-cough, 17 to diarrhœa, 15 to measles, 6 to diphtheria, 2 to "fever," 1 to scarlet fever, and not one to small-pox. In all, 63 deaths resulted from these principal zymotic diseases, against 66 and 73 in the preceding two weeks. These 63 deaths were equal to an annual rate of 2·3 per 1000, which was 0·5 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 30 and 24 in the preceding two weeks, further declined last week to 22, of which 11 occurred in Glasgow, 4 in Aberdeen, and 3 in Dundee. The 17 deaths from diarrhœa considerably exceeded the number in any recent week, and included 6 in Glasgow, and 3 each in Edinburgh, Dundee, and Aberdeen. The fatal cases of measles, which had been 14 and 18 in the previous two weeks, declined again to 15 last week, of which 14 were recorded in Glasgow. The 6 deaths referred to diphtheria showed a decline of 4 from the high number in the preceding week, and included 3 in Glasgow. The fatal case of scarlet fever occurred in Paisley. The deaths referred to diseases of the respiratory organs in these towns, which had been 160 and 130 in the preceding two weeks, rose again last week to 163, and exceeded by 20 the number in the corresponding week of last year. The causes of 60, or nearly 10 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the preceding four weeks from 40·1 to 30·6 per 1000, rose again to 35·8 during the week ending April 23rd. During the first three weeks of the current quarter the death-rate in the city averaged 33·1 per 1000, the rate for the same period being 20·9 in London and 19·6 in Edinburgh. The 240 deaths in Dublin during the week under notice showed an increase of 35 upon the number in the preceding week, and included 33 which were referred to measles, 10 to whooping-cough, 2 to diarrhœa, 1 to "fever," and not one either to small-pox, scarlet fever, or diphtheria. In all, 46 deaths resulted from these principal zymotic diseases, equal to an annual rate of 6·9 per 1000, the zymotic death-rate during the same period being 3·3 in London and 1·4 in Edinburgh. The fatal cases of measles, which had declined from 24 to 14 in the preceding three weeks, rose again last week to 33, a higher number than has been recorded in any week since July, 1887. The deaths referred to whooping-cough, which had been 3 and 5 in the previous two weeks, further rose to 10 last week. The 2 fatal cases of diarrhœa corresponded with the number in the preceding week. Only one death was referred to "fever," against 6 in the previous week. The 240 deaths registered in Dublin last week included 43 of infants under one year of age, and 46 of persons aged upwards of sixty years; the deaths of infants showed a marked increase, while those of elderly persons showed a further decline from recent weekly numbers. Six inquest cases and 3 deaths from violence were registered; and 71, or nearly a third, of the deaths occurred in public institutions. The causes of 28, or nearly 12 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

NEW REGULATIONS FOR ADMISSION TO THE ARMY MEDICAL STAFF.

THE attention of all intending candidates for the Army Medical Staff is called to these regulations, which have been furnished to us by the Director-General, regarding some additional requirements to the existing qualifications for admission to examination:—"The following will be inserted after paragraph 2 in the Regulations issued with Army Order 242 of 1891: 2A. After March 31st, 1893, every candidate for a commission in the Medical Staff of the Army must produce, in addition to the documents specified in paragraphs 1 and 2—(1) A certificate of having discharged the duties of a medical clinical clerk during six months, and of a surgical dresser during another period of six months, of which, in each case, not less than three months must have been spent in the wards of a hospital. (2) A certificate of having attended a course of instruction during not less than three months at an Ophthalmic Hospital, or the Ophthalmic Department of a general hospital, which course shall include instruction in the errors of refraction."

ARMY MEDICAL STAFF.—Surgeon-Lieutenant-Colonel H. W. A. Mackinnon, D.S.O., has taken over the charge of the 3rd Station Hospital, Aldershot.—Surgeon-Lieutenant-Colonel E. Townsend has been appointed to the Station Hospital, Mandalay; Surgeon-Captain M. F. Macnamara to duty in the Secunderabad District; Surgeon-Captain G. H. Younge to the Station Hospital at Malapuram; Surgeon-Captain H. E. Dowse to duty in the Belgaum and Bangalore Districts; Surgeon-Captain F. A. B. Daly to the Station Hospital, Wellington; Surgeon-Captains F. S. Le Quesne, V.C., and J. Donaldson to the Belgaum and Bangalore Districts; Surgeon-Captain J. F. Donegan to the Station Hospital, Belgaum.—Surgeon-Major-General Alfred Malpas Tippetts is placed on retired pay (dated April 5th, 1892); Surgeon-Colonel Thomas Norton Hoysted to be Surgeon-Major-General, vice J. Sinclair, M.D., retired (dated March 28th, 1892); Brigade-Surgeon-Lieutenant-Colonel Thomas Maunsell to be Surgeon-Colonel, vice C. H. Y. Godwin, seconded (dated March 10th, 1892); Brigade-Surgeon-Lieutenant-Colonel Alexander Francis Preston, M.B., to be Surgeon-Colonel, vice T. N. Hoysted (dated March 28th, 1892); Surgeon-Lieutenant-Colonel Henry William Alexander Mackinnon, D.S.O., to be Brigade-Surgeon-Lieutenant-Colonel, vice T. Maunsell (dated March 10th, 1892); Surgeon-Lieutenant-Colonel James Lane Notter, M.D., to be Brigade-Surgeon-Lieutenant-Colonel, vice A. F. Preston, M.B. (dated March 28th, 1892); Surgeon-Captain Wm. Jones Crofton, M.B., is placed on temporary half-pay on account of ill-health (dated April 7th, 1892).

INDIAN MEDICAL SERVICE.—Surgeon-Major Russell, M.B., B.Sc., Civil Surgeon, Patna, and Principal, Temple Medical School, goes to Darjeeling as Civil Surgeon; Surgeon-Major Nicholson takes his place at Patna.—Surgeon-Major Owen, on return from furlough, takes up his post of Surgeon to his Excellency the Commander-in-Chief.—Dr. Edwards, Surgeon to the Commander-in-Chief, will proceed to Quetta, where he has been appointed Civil Surgeon.—Surgeon-Colonel R. Harvey, D.S.O., is transferred from the administrative medical charge of the Punjab Frontier Force

Digitized by Google

to that at Calcutta, vice Surgeon-Colonel J. C. Morice, proceeded to England on leave.

NAVAL MEDICAL SERVICE.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon Brien Patrick Sarsfield McDermott has been placed on the Retired List of his rank (dated April 15th, 1892).

MILITIA MEDICAL STAFF.—Surgeon-Major T. Allman, 3rd Battalion the Connaught Rangers, to be Surgeon-Lieutenant-Colonel (dated April 23rd, 1892).

VOLUNTEER CORPS.—*Artillery:* 3rd Kent (Royal Arsenal): Surgeon-Lieutenant-Colonel W. W. Coleman resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Corps on his retirement (dated April 23rd, 1892).—*Royal Engineers:* 1st London: Lieutenant Sidney Reginald Dyer, M.D., to be Captain (dated April 13th, 1892).—*Rifle:* 3rd Volunteer Battalion, the South Staffordshire Regiment: Thos. Ridley Bailey, M.D., to be Surgeon Lieutenant (dated April 23rd, 1892).—1st (Inverness-shire) Highland Volunteer Battalion, the Queen's Own Cameron Highlanders: Surgeon-Lieutenant J. Macrae, M.D., resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Battalion on his retirement (dated April 23rd, 1892).—20th Middlesex (Artists'): Henry Darville Brook, Gent., to be Surgeon-Lieutenant (dated April 23rd, 1892).

VOLUNTEER MEDICAL STAFF CORPS.—The Edinburgh Company: Surgeon-Lieutenant W. H. Barrett, M.B., resigns his commission (dated April 23rd, 1892).

Correspondence.

"Audi alteram partem."

THE MEASLES BACILLUS.

To the Editors of THE LANCET.

SIRS,—In the last issue of THE LANCET attention is directed to a paper by Drs. Canon and W. Pielicke, published in the *Berliner Klinische Wochenschrift*, on the Bacillus of Measles. The work of English observers is seldom noticed in French or German journals. It is incomprehensible that an observation of this kind, which I made fifteen years ago, and which was fully described and illustrated in the "Third Contribution to the Life-History of Contagium,"[1] should have its originality dedicated to the Germans. Original work done in this country receives scant recognition. I exhibited slides showing these spores and bacilli at the conversazione of the Royal Society on April 25th, 1883, and at a meeting of the London Pathological Society in May, 1878. I found the bacillus of measles in the breath, lung tissue, and skin of patients. Dr. Ransome of Manchester published in the Transactions of the Literary and Philosophical Society of Manchester, 1869, similar observations on the breath of measles patients. Since then Dr. J. M. Keating, M. Le Bel, and others, have obtained this bacillus and cultivated it. In Dr. Quain's "Dictionary of Medicine" (1882), art. Measles, I find my discovery mentioned. For the credit of English scientific medicine, which in many respects is on a par with continental work, I trust you will draw attention to this letter.

I am, Sirs, yours obediently,

P. MURRAY BRAIDWOOD.

Willesden-green, N.W., April 26th, 1892.

To the Editors of THE LANCET.

SIRS,—The bacilli found in the blood of patients with measles are said by the observers, Drs. Canon and Pielicke, to be different from the micro-organisms hitherto described in connexion with that disease. They refer to the work of MM. Cornil and Babes, Paris, 1886, where a short bacillus is mentioned in this connexion; but not to our Pathological Society's Transactions for 1878, p. 422, where Dr. Braidwood and Mr. Vacher describe elongated bodies with abrupt ends found in the breath of children during measles; also p. 422, "Sparkling, spindle-shaped, staff-shaped, or canoe-shaped bodies" after death, probably the germs or organisms with which the contagium of measles is intimately associated. Again, in the lung "staff-shaped, fusiform, or ovate bodies, slightly tinged with carmine, and appearing as dark rods," are sufficiently distinguished from the pneumococci of other pulmonary inflammation. It cannot be said that Dr. P. M. Braidwood and Mr. Vacher attached no importance to these bacilli, and it seems to me that they are in no way essentially different from those found by Drs. Canon and Pielicke in the blood of patients suffering from measles.—I am, Sirs, yours &c.,

WILLIAM SQUIRE, M.D., F.R.C.P.

Harley-street, W., April 26th, 1892.

[1] Brit. Med. Jour., 1882.

"THE SMOKE NUISANCE."

To the Editors of THE LANCET.

SIRS,—The letter of my friend, Mr. Thomas Bond, advocating support for an Act of Parliament to deal with "the smoke nuisance," suggests the question whether it would not be better to see how this can be done before asking Parliament to undertake what is impossible, until a reasonable remedy is at least proposed to it. The exhibition at South Kensington a few years ago did not result in any simple solution of the question, and I doubt whether you would feel disposed to encourage the discussion of a subject which belongs rather to the province of the chemist or the engineer than to that of medical science, but for the circumstance that there are questions of health of great importance connected with it. The origin of the smoke nuisance is to be traced in the method of burning soft coal in open fireplaces which find favour in this country. Now the first step towards curing the "smoke nuisance" is to make the public fully appreciate the fact that this custom is attended with such enormous waste and pecuniary loss as to make the matter of economy quite as deserving of thought as that of the "nuisance." It may be fairly calculated that no profit is derived from half the coal burnt in domestic fire places, that is so far as benefit is obtained for warming purposes. More than half the heat generated by the coal goes up the chimney, and is absolutely wasted. What the actual cost of the coal in London may be, which is consumed in open fireplaces, I am not able to state; but it must be over £2,000,000 per annum; and if so, £1,000,000 is lost by waste. In order to perceive that this is a matter of medical interest, we must realise that in the use of open fireplaces the question of ventilation is involved to as great an extent as that of warmth; and it would be fair to ask whether sanitary requirements demand the amount of ventilation obtained by open fireplaces. If we go to the other extreme and consider the great defects in ventilation which attend the use of closed stoves, we shall be able to appreciate the nature of the problem which has to be determined before we can fairly ask Parliament to interfere. Now medical science has settled the question of ventilation, just as accurately as it has decided the areas, superficial and cubical space, which are necessary for apartments of all kinds. It would be quite easy to prove that open fireplaces produce an amount of ventilation which science does not require; and that while the stove on the one hand is seriously injurious to health, the open fireplace on the other is not only wasteful of heat and causes in one way too much ventilation, but is nearly as injurious to health as the other by the smoke it produces. To medical science, then, the public has a right to put the question, What amount of ventilation ought to be provided in an apartment of any given dimensions? and this being already answerable, the problem simply reduces itself to determining the mean between the open fireplace and the closed stove, or to such an arrangement as would reduce the waste of up-draught in chimneys to the requirements of health. There is a mean which can be arrived at without much difficulty, but that is not a subject which would interest your readers, as it is connected with physics, the combustion of coal, and the laws of ventilation. Let this question of waste, which I think I have greatly under-estimated, of gigantic useless waste, be appreciated by the public, and the remedy will soon be found.

I am, Sirs, yours truly.

Savile-row, W., April 23rd, 1892. ROBERT LEE.

SMALL-POX TRAMPS: WHO IS RESPONSIBLE?

To the Editors of THE LANCET.

SIRS,—My attention has just been called to a letter in your issue of the 23rd inst., purporting to give an account of the treatment which a small-pox-infected pauper has received here, and to your comments thereon. As this case has caused considerable feeling throughout North Wales, and as your comments reflect discredit upon the action of the urban sanitary authority over which I have the honour to preside, may I ask you, in justice to myself, the chairman of the sanitary committee, and the medical officer of health who had the matter in hand, to give space for the publication of our version of the case? The first notification we received was in a letter from the chairman of the infirmary committee to our medical officer, which stated: "A tramp came to the infirmary this morning, and he is pronounced to be ill from small-pox; in the meantime he is put in an isolated room." Next we received a certificate in which he was referred to as "an inmate of the infirmary." How he got into the institution it was not our duty to inquire, but our medical officer, on visiting the place, found him located in a room known as the fever ward, which is more or less apart from the rest of the infirmary, and into which infectious patients have from time to time been received. The Infectious Diseases Prevention Act has been adopted in this borough, but so far it has not been thought necessary to avail ourselves of the permission given in the Public Health Act of 1875 to public authorities to provide a fever hospital, the town being a small one, and outbreaks of this kind very infrequent. And even had such a hospital been provided, it is doubtful what use it would have been, as the sanitary authority have no power to remove a patient into hospital unless he is "improperly housed or living in a room which is occupied by more than one family," neither of which reasons held good in this case. Consequently we had no means of finding shelter for this patient, which would not have endangered the lives of the townspeople generally.

The duties of a sanitary authority, under circumstances of this kind, are most clearly defined by law, and we carried them out to the best of our ability. We took immediate steps to destroy the bedding on which the tramp had slept the previous night, and to disinfect the common lodging-house. We considered that the fever ward at the infirmary, in which he had been kept all day, was already infected by his presence, and that it was our duty to take every precaution to isolate him there. We were doing so, when the extraordinary announcement was made to us that he had been turned out of the infirmary, at about half-past seven o'clock at night, by the authorities. We, or rather the union authorities, were therefore compelled to find him a shelter in the same common lodging-house in which he had passed the previous night, kept by an old man and his wife. Here he has since been isolated as far as possible, though the house is situated in the midst of the most thickly populated district in the town. The case happened on a Thursday. On the following Tuesday the parish doctor, who is also one of the medical officers of the infirmary who ejected the man, visited him for the first time. Naturally, this has caused a great deal of ill-feeling in the neighbourhood. These are the facts of the case. If you are still of the "opinion that the sanitary authorities were the principal culprits," perhaps you will kindly state in your notes what steps you consider should have been taken by them, and also by what authority or Act of Parliament they should have been guided.

I am, Sirs, your obedient servant,
T. A. WYNNE-EDWARDS, Mayor of Denbigh.
April 27th, 1892.

UTERINE DILATATION.

To the Editors of THE LANCET.

SIRS,—When the idea first occurred to me of dilating the uterus by means of continuous elastic pressure I employed conical plugs surfaced with a wide and swiftly travelling screw, precisely the same as those recommended by Dr. Reid. I tried them both by manual rotation, and by a simple method of continuous gentle elastic tension. I found, however, that while they acted as a rule fairly well, every now and then they gave rise to inflammatory trouble. I therefore adopted the simple conical plug, and applied the distending force from a waist belt as described in THE LANCET of Nov. 1st and 8th, 1879. Since then a few improvements in detail have been effected, and now they are made absolutely perfect by Messrs. Lynch and Co. (Aldersgate-street(of aluminium. This system of dilatation of the uterus has been employed in my practice many hundreds—I think I may say thousands—of times, and has not given rise in any one instance to the slightest cause for alarm. The apparatus is practically automatic, and the process throughout requires only a very few moments' attention. If conducted slowly it is free from pain, but should circumstances require a rapid dilatation, this can easily be secured by the aid of a morphia syringe.—I am, Sirs, yours truly,

Birmingham, April 23rd, 1892. LAWSON TAIT.

OPERATION FOR SPASMODIC TORTICOLLIS.

To the Editors of THE LANCET.

SIRS,—The letter in THE LANCET of April 23rd upon the above subject from Dr. Alexander Harkin hardly, I think, applies to cases of *confirmed* spasmodic wry-neck. That some cases of a neurotic nature may simulate such an affection and be cured by such a simple method as the application of a blister may be perfectly true, but that cases like that first operated upon by Campbell de Morgan, and those recorded by myself, and published in my recent pamphlet upon "Spasmodic Wry-neck," were of this kind is not, I think, a reasonable deduction. Ablation of a piece of the nerve or nerves supplying the offending muscles does not probably get to the root of the evil, but that patients whose lives have been a misery to them are by this operation relieved is a fact, which will have far greater influence with practical surgeons and suffering victims of the disease than any amount of objection based upon theoretical or sentimental grounds. To describe, as Dr. Harkin does, a practically safe but, perhaps, somewhat difficult operation as "vivisection" seems to me absurd; but to urge that operative measures should not be undertaken unless absolutely necessary is a reasonable argument. I will leave it for others to judge whether the cases in which I have operated, and to which you refer in your annotation, were undertaken without sufficient necessity. In the first one violent and continuous spasms had existed for sixteen years, and in the other for six years. Both patients had been subjected to extensive treatment by drugs innumerable, and by electricity, without the smallest benefit, while since the operations they both remain perfectly well. In the first case the period of immunity has now reached two years, and in the other one year. In conjunction with these patients, and apparently in opposition to Dr. Harkin, I venture to suggest that treatment by operation is a far less severe one than that previously employed in these cases. I have lately operated upon two other patients, but sufficient time has not elapsed to judge of the result.

I am, Sirs, yours faithfully,

Queen Anne-street, W., April 23rd, 1892. NOBLE SMITH.

MEDICAL DEGREES FOR LONDON STUDENTS.

To the Editors of THE LANCET.

SIRS,—The recent pass list for the M.B. of the University of Durham illustrates the wants of the London medical student in the matter of degrees. It will be found that the whole list comprises forty successful candidates, of whom fourteen only came from the Newcastle College of Medicine; and of the remaining twenty-six, eighteen came from the following London schools: St. Bartholomew's, 5; St. Mary's, 5; Guy's, 4; St Thomas's, 2; Middlesex, 2. As the Durham degree necessitates one year's residence in Newcastle, it is obvious that these eighteen candidates must have incurred some considerable additional expense in order to attain their object.

I am, Sirs, yours obediently,

April 26th, 1892. A LONDON TEACHER.

NEW ZEALAND.—John Hay Honeyman, M.D. St. And., L.R.C.P., L.R.C.S. Edin., was entertained on Jan. 26th last at a complimentary supper by the members of the Auckland Branch of the New Zealand Medical Association, in recognition of his having presented the branch with the nucleus of a medical library.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Influenza.

THIS city has, as has been previously shown in THE LANCET, been remarkably free from influenza during this year's epidemic. Cases have, it is true, been constantly occurring up to the present time. Since the commencement of February the medical officer of health for the city, Dr. Tatham, has sent out special weekly forms, with the purpose of obtaining trustworthy returns of the cases of this disease occurring in hospitals and dispensaries and in the home-patients' districts attached to the various hospitals. The total number of cases thus returned was 28 in the week ending April 16th, whereas in the three previous weeks it had been 42, 65, and 78. A constant and steady decline is thus shown. The deaths attributed directly to the epidemic were 7 in number last week, a slight increase on the deaths in the two previous weeks. Neighbouring towns and surrounding districts appear to have suffered much more severely from influenza than Manchester itself has. However, the continued occurrence of cases makes it appear possible that a more severe outbreak may still occur. Last year's epidemic did not assume great severity till the commencement of May. Several cases of pneumonia and acute phthisis have even now come under notice which, apparently, were sequels of attacks of influenza.

Small-pox.

Some apprehension has been caused by the appearance of small-pox. Altogether, however, only five cases from the city of Manchester have been reported. The admissions to the fever hospitals for this disease are, however, diminishing, and it may reasonably be hoped that the outbreak will not be of a serious nature. There have been no fatalities.

Healthy Homes Society.

This Society, which has existed for two years, has for its object the instruction of the working classes in the direction of the sanitary improvement of their houses and of their mode of life. It has so far had a great success, the attendances at the meetings increasing steadily. Last week Dr. Harris, physician to the Royal Infirmary, gave a short lecture on "Germs and their Influence in producing Disease," and was listened to with great attention by a crowded audience of precisely the class of people for which the society exists—operatives from the mills and factories of one of the largest industrial districts of the city.

The Spreading of Infectious Disease.

Another case of alleged ignorance of the law and certainly of the greatest thoughtlessness came before the stipendiary magistrate last week. A child known to be suffering from scarlet fever was conveyed by its relatives in a cab half way across the town. Before the sanitary authorities could make an order for disinfecting the vehicle it had been again used by several healthy persons. Such cases are of too common occurrence. The fine of one pound on each defendant may help to remind them in future that ambulances for the conveyance of fever patients are kept by the Corporation, and are at the service of those wishing to have infectious patients removed.

Manchester, April 27th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Strikes and Distress in the North.

IT is stated that the engineers' strike will be settled, and that most of the men will return to their work this week. Meantime, it is calculated that the loss of wages on the Tyne and Wear during the past twelve months will amount to the enormous total of one million pounds, while the distress produced by this enforced idleness has been very far reaching and severe. Great collective and individual effort has been made by all classes to mitigate this. For instance, since Christmas 10,000 children have received breakfast at the Bath-lane Hall, Newcastle, and soup kitchens have been opened in nearly every district in the city. At South Shields and district the distress has been very severe. On Saturday last about a thousand children received a substantial midday meal at the Royal Assembly Rooms in that town, the funds being raised for the purpose by two ladies; and a large number have been fed at breakfast, the number of meals provided in this way being over ten thousand. Still, when all has been done, there must have been very much suffering; so that we are all pleased at the prospect of the strike coming to an end. The chief constable of Newcastle, Captain Nicholls, in his report for the last quarter, states that there has been a decrease of felonies and misdemeanours as compared with the corresponding quarter of last year. Drunkenness also shows a considerable decrease, and he further says: "It is only right that I should acknowledge the exemplary good conduct of the working classes throughout the existing strike."

Newcastle Nurses' Home.

The annual meeting of the Newcastle Nurses' Home has been held, and a very satisfactory account has been given of the last year's operations of the institution, showing that at present there are fifty-nine trained nurses and ten probationers on the staff. The house in Ellison-place was still retained by the committee for the reception of patients attended by their own medical advisers. During the year the nurses had attended 445 cases. Dr. Black was thanked for his kind attendance, as well as Mrs. Barnes for her donation of £100.

Scarlatina in the Hexham Union.

At the last meeting of the Hexham Union rural sanitary authority the medical officer reported forty cases of scarlet fever, which were principally in the Stocksfield district, in children attending a school, which it had been considered advisable to close for a while.

Small-pox and Football.

At the monthly meeting of the Hartlepool port sanitary authority attention was drawn to the risk the town would run of being infected with small-pox should an advertised match take place with the Batley team at the former place. It was shown that the risk was not so much from the players as from their followers from Batley, and, taking into account the lateness of the season for football, and the fact that, should the Hartlepools become infected, it would be a serious thing for all vessels leaving the port, which would involve their detention in quarantine for a certain period. I have not heard that these matters were taken into account; I hope so, and that the match has been cancelled.

Ambulance Work in the North.

The members of the North-Eastern Railway Company's Servants' Ambulance Class, at Consett and Blackhill stations, have been examined by Dr. Jepson of Durham. The class, which has a good number of members, underwent their exercises in such a manner as to call forth the highest praise from the examiner. The conductor of the class was Dr. Macintyre of Consett. The Mayor of Tynemouth has presented certificates to seamen at North Shields. The class has not been long formed, but 108 sailors have been enrolled. A course of lectures has been given by Dr. F. C. Mears of North Shields to an average attendance of 71 pupils, and 27 of these have been examined and passed by Dr. Squance of Sunderland. The Mayor, in making the presentations, spoke of the advantages of ambulance knowledge to the seafaring classes. The Cullercoats Volunteer Life Brigade has just received a splendid addition to the library, which was formed in the brigade house a few years ago. Messrs. Cassell and Co. have gratuitously forwarded a complete set of their "National Library," which is an almost entire representation of our national literature, containing upwards of 300 volumes. The hearty thanks of the brigade has been forwarded to Messrs. Cassell and Co. for this valuable gift.

Darlington Hospital.

The third annual ball in aid of the funds of the Darlington Hospital has taken place after its postponement by reason of the death of the Duke of Clarence and Avondale. There was a considerable decrease in the attendance owing to the postponement, but it is not anticipated that the hospital funds will suffer any loss, owing to the fact that several special subscriptions have been handed in to prevent this.

Digitized by Google

"German Sausages."

At the Gateshead Police-court a case of alleged ill-treatment of a pony was recently dealt with. The inspector stated that the animal in question was unable to travel, and he found it being taken from Gateshead to Newcastle. He further explained to the bench that a higher price was given for a live animal at a certain yard in Newcastle, where animals, after being killed, were cut up and packed in barrels and forwarded to Antwerp, where the flesh was made into German sausages.

The Fatal Lamp.

An inquest was held at Sunderland on Monday last upon the body of a woman aged sixty-eight, who died from the effects of burns received on Saturday night. It was shown that the lamp exploded, and that the deceased was in the habit of blowing it out, which, the coroner remarked, was a very dangerous habit. The verdict was in accordance with the evidence.

The late Mr. E. M. Bainbridge, J.P., of Newcastle, who in his lifetime was a munificent benefactor to our charities, bequeathed about £7000 to various medical and religious institutions, and directed all to be paid free of legacy duty, including the following: Newcastle Royal Infirmary, £1000; Newcastle Dispensary, £1000; Newcastle Blind Asylum, £1000; Fleming Memorial Sick Children's Hospital, Newcastle, £1000.

I hear that Mr. Frederick Page of this city has been offered the post of hon. consulting surgeon to the City Lunatic Asylum, in the place of the late Dr. Heath.

Newcastle-on-Tyne, April 27th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University General Council.

THE statutory half-yearly meeting of this body was held last week. The Vice-Chancellor, Sir William Muir, presided. There was only a small attendance. A report on behalf of the Council's Committee on Communications to the University Commissioners was submitted by Mr. Taylor Innes, advocate. The general conclusions of the report were that the ordinances, as a whole, should be reconsidered, and for that reason should be opposed by a petition to Her Majesty, praying her to withhold her consent from the ordinances as issued, an exception being made in the case of the ordinance on the graduation of women. The committee asked for powers to cooperate with the representatives of other University councils and others who might have an interest in the matter. The ordinances, it appears, are now out of the hands of the Commissioners, and it is not competent for them to change what they had done; and the best means provided by the statute for their reconsideration was, in the opinion of the committee, by approaching the Privy Council through the House of Commons. The recommendations of the committee were carried, only two dissenting. From this it will be seen that the action of the General Council, and probably of the Association for the Reform of Medical Education also, is about to develop another stage in trying to influence Parliament.

Health of Edinburgh.

The mortality last week was 82, and the death-rate 16 per 1000. Diseases of the chest accounted for 28 deaths and zymotic diseases for 4. The intimations for the week were: Typhoid fever, 5; diphtheria, 4; scarlatina, 34; measles, 40.

Opening of the Summer Session in Edinburgh.

The summer session in the Medical Faculty will open on Tuesday, May 3rd. Most of the lecturers and professors in the school have been out of town during part of the current month, but the end of the week will see most of them back.

Public Health in Glasgow.

In Glasgow there were in the past fortnight 684 deaths registered, an advance of 45 as compared with the fortnight preceding, and giving a death-rate of 26·6 instead of 24·8 per 1000. Two of the deaths were from typhus fever, of which ten cases were reported. In connexion with this outbreak, Dr. Russell remarks that it well illustrates both the direct punishment brought on those who overcrowd and the indirect injury done to others who may be living in unexceptionable circumstances. In the southern district, which is notorious for overcrowding, four cases occurred, in two one-apartment houses, both overcrowded; the victim in one case is a person who has been previously fined for this offence. In quite a different locality, in a house of three apartments, a solitary case occurred in the person of a young man who, it was discovered, had visited a house which consists of two overcrowded apartments, 11½ adults occupying the cubic space of 5½ adults, according to the Glasgow standard. Of these adults, ten are under treatment for typhus fever.

Queen Margaret College.

In a report presented at a recent meeting of those interested in this College it was stated that 203 students had matriculated during the past session. In the medical school there were 27—namely, 12 in the first year, 11 in the second, and 4 in the third. In the medical school a scholarship of £25, founded by Mr. Arthur of Barshaw, and to be held for three years, will be awarded in October next. Reference was also made to the bazaar, by which it is hoped to raise the College funds to £25,000. It was further stated that the affiliation of the College to Glasgow University would probably become an accomplished fact in the course of the summer.

April 26th.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Consulting Physicians to Irish Asylums.

THE controversy still rages, and the latest contribution to the subject is a statement issued by Mr. Conolly Norman, medical superintendent of the Richmond Lunatic Asylum, who is the Irish secretary of the Medico-Psychological Association of Great Britain and Ireland, setting forth why a repeal of the Privy Council Order providing for the future abolition of the office of consulting physician would be very undesirable in the interests of the insane, and of the proper management of asylums in this country. Mr. Norman expresses the hope that those who are responsible for the recent reform in the Privy Council rules will pause before they yield to the clamour which has been raised for their repeal, and considers that to retain the office of visiting physician will be to go against the current of modern opinion on this subject, and to disregard the views so plainly expressed by the many committees of visitors of English and Scotch asylums, who have during the last forty years given their gratuitous services to the insane with such brilliant results.

Royal College of Surgeons.

The candidature of Mr. Nixon for a seat on the Council, referred to last week, is for a by-election and not for the general election of office-bearers in June next. The vacancy has arisen owing to the resignation of Mr. Stoker, and will be filled up on May 2nd.

Dublin Hospital Flower Mission.

The South Dublin Hospital Flower Mission distributed last season upwards of 23,000 miniature bouquets to the sick and suffering in hospital wards in the city. Last week the Earl of Annesley forwarded over 12,000 daffodils from the Park at Castlewellan to the North Dublin Flower Mission, for distribution among the hospitals on the north side. The amount of pleasure given to the sick and weary by these silent messengers of sympathy is incalculable.

Zymotic Diseases in Dublin.

During last week the deaths from zymotic diseases amounted to 55, being 34 in excess of the average for the corresponding week of the last ten years, and 19 over for the week ended the 16th inst. Measles still prevails, and on last Saturday there were 174 cases of the disease under treatment in the various city hospitals.

April 26th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A Case of Hermaphroditism.

THE case recently reported by M. Boekel of Strasburg to the Académie de Médecine being, so far as I know, unique, I have deemed it worthy of record in your columns. The subject of this vagary of Dame Nature is a man aged twenty years, who since his birth had suffered from inguinal hernia. He readily agreed to the proposal of a radical cure, the operation for which yields some surprises. The hernial sac was found empty, but in its posterior wall there was found, covered by peritoneum, a triangular body, which was supposed to be an intestinal diverticulum. Further examination, however, showed that the inguinal canal was empty, and that the organ in question had no connexion whatever with the digestive tube. Compression of the abdomen above the ring resulted in the extrusion through the external inguinal ring of an ovoid pearly body resembling the testicle. Lying parallel and above this body, and united to it, was a fringed cystic organ, which could not be anything else but the Fallopian tube. All these strange structures were carefully isolated by a process of dissection and extirpated. Cicatrisation was complete at the end of ten days. Examination of the extirpated mass revealed (1) a bicornate uterus, the mucous membrane of which was lined by ciliated epithelium; (2) a Fallopian tube and a testicle provided with an epididymis and a vas deferens; (3) a broad ligament enclosing these organs. This is the only known example of female sexual organs being contained in the scrotum of a man whose physical conformation would certainly not have given rise to a suspicion of any such mixture of the sexes.

New Treatment of Dupuytren's Contraction of the Fingers.

The introduction of antiseptic principles into the field of surgery has had the effect of rendering operators more adept in their measures, and consequently nothing which falls short of thoroughness will satisfy the modern surgeon, even when the disease he has to remedy is nothing more than an infirmity. When, years ago, Adams devised his method of multiple subcutaneous divisions of the retracted palmar fascia for the cure of that comparatively common condition, contraction of the fingers, surgery was supposed to have done its utmost in this direction. But time showed that relapses were not uncommon after this operation; and now M. Berger tells us (Académie de Médecine, April 19th) that nothing short of complete extirpation of the retracted fasciculi of the palmar fascia, together with the overlying and adherent skin, can bring about a permanent cure of this condition. The loss of substance thus caused is repaired by the Taliacotian operation—viz., the insertion into the wound of a skin flap derived from the trunk and left adherent by its pedicle until its complete adherence to its new bed is assured (autoplasty by the modified Italian method). M. Berger presented a patient who had been operated on by the above method. The inserted flap was supple, movable on the surrounding parts, sensitive and healthy, and no tendency to recurrence of the contraction was present.

On the Use and Abuse of Mercury in Eye Diseases.

Professor Panas states (Acad. de Méd., 26th inst.) that he cannot agree with M. Landolt in his view that mercurial medication is useful only in ocular diseases of syphilitic origin. M. Panas has frequently seen cases of non-syphilitic plastic iritis and choroiditis, as also myopic sclero-choroiditis, greatly benefited from the administration of a salt of mercury. But all depends on the mode of introducing the metal into the system. M. Panas prefers the hypodermic method, and he employs for this purpose a solution of mercuric iodide in sterilised olive oil. Each injection (a Pravaz syringeful) contains from four to five milligrammes of the salt, and it is repeated every day or every other day, according to the susceptibility of the subject. If the solution be introduced into the muscular mass of the loins or the buttocks, no fear of abscess or induration need be entertained. The introduction of a total quantity of ten or fifteen centigrammes, spread over an interval of one or two months, has often sufficed to cure the above maladies without provoking any gastric or other inconveniences.

Rumoured Appearance of Cholera in Paris.

Alarming rumours of the appearance of the dread disease cholera in our midst have recently been published in lay journals, and, however unfounded such reports may be, it is only right that they should not be allowed to pass unnoticed in your columns. The abrupt atmospheric changes to which we have been treated of late are doubtless responsible for the somewhat numerous cases of diarrhœa which every Paris practitioner has recently been called upon to treat. When these cases begin to flow into the hospitals it is easy to understand how the cry of "cholera" arises. In this morning's medical papers not one word is said of such cases, nor is the word "cholera" mentioned. In the last *Bulletin Hebdomadaire de Statistique Municipale* only one death from diarrhœa in persons above the age of five years is reported. In order to bring my information up to date, I have just paid a visit to the Beaujon Hospital, which is said to have been the scene of the recent cholera epidemic. I am informed that five adults out of a batch of six recently admitted with symptoms much resembling cholera have succumbed at that institution. One, the remaining case, is still under treatment, transfusion of serum having been practised. The staff hope to save this patient. All these persons hail from Nanterre, a village distant from Paris about five or six miles, and situated in the valley of the Seine. No similar cases have been admitted into any other Paris hospital. Too much stress cannot be laid on the fact that not one of the victims of a disease which is certainly not cholera was an inhabitant of this capital. Bacteriological and other researches are proceeding with regard to this strange occurrence, and the results will be duly published in the columns of the medical press. It only remains to state that the general health of Paris is satisfactory.

Application of the Sclerogenic Method to the Treatment of Ununited Fracture.

M. Ménard reported to the French Surgical Congress the cure of a case of ununited complicated fracture of the leg which had resisted the usual methods of complete immobilisation for five months. M. Ménard injected into the insufficient callus 1 gramme 25 centigrammes of a 10 per cent. solution of zinc chloride. From that moment consolidation made rapid progress, and in a month the patient began to walk. Here we have another success scored for the method devised by Professor Lannelongue.

Paris, April 27th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Eleventh Congress for Internal Medicine.

THE eleventh Congress for Internal Medicine met at Leipsic on the 20th inst., Professor Curschmann in the chair. The assembly was very numerous, and included Professors Leyden, Ehrlich, Senator, Fürbringer, Fräntzel, A. Fränkel, and Guttmann of Berlin, von Ziemssen of Munich, Nothnagel of Vienna, Mosler and Landois of Greifswald, Lichtheim of Tübingen, Bäumler and Thomas of Freiburg, Ebstein of Göttingen, Immermann of Bâle, Rosenbach and Neisser of Breslau, Edgreen of Stockholm, Unverricht, Stadelmann, and Dehis of Dorpat, and Martius of Rostock. Almost all the medical professors of Leipsic were present. After the chairman's opening address and speeches of welcome, from the Minister of Education, the Burgomaster of Leipsic, and the Rector of the University, Professor Birch-Hirschfeld spoke on "Severe Forms of Anæmia." The discussion filled up the afternoon, and there was a great banquet in the evening. In the forenoon sitting on the 21st the subjects were diabetes mellitus, the diet of diabetic patients, and immunity. On the same day Dr. Binswanger of Constance spoke on hypnotism and suggestion, and Professor Klebs of Zurich on the treatment of tuberculosis with tuberculocidin—i.e., tuberculin as purified by him. He has treated 130 tuberculous patients, and reported excellent results.

Statistics of Suicide.

The number of suicides between the ages of ten and fifteen in Prussia in 1890 was 2·2 per 100,000 of the population, between fifteen and twenty 13·3, between twenty and twenty-five (in which the period of military service generally lies) 22 5, between twenty-five and thirty 21 7, between

Digitized by Google

thirty and forty 24·7, between forty and fifty 37 5, between fifty and sixty 45·8, between sixty and seventy 50 2, between seventy and eighty 58 9, above eighty 68·3.

A Homœopathic Hospital.

The Berlin Society of Homœopathic Doctors, in conjunction with several other homœopathic societies here, recently petitioned the magistrates of Berlin to establish a special homœopathic hospital, or at least to set apart a ward in one of the city hospitals for patients who wish to be treated homœopathically. The magistrates have resolved to reject this request, on the ground that it is not expedient to establish a special hospital for the adherents of a special therapeutic system deviating from that of modern medical science.

A New Balneological Association.

Several physicians at watering-places and heads of bathing establishments have founded a General German Balneological Association at Leipsic.

Statistics.

In the week which ended on the 9th inst., 1 person died here of erysipelas, 1 of puerperal fever, 1 of articular rheumatism, 1 of syphilis, 3 of scarlatina, 5 of typhus fever, 7 of influenza, 8 of measles, 9 of whooping-cough, 9 of diarrhœa, 9 of diarrhœa with vomiting, 11 of cerebral apoplexy, 17 of diphtheria, 19 of gastro-intestinal catarrh, 27 of senile decrepitude, 70 of pneumonia, and 102 of pulmonary phthisis. There were 2 deaths by poison, 1 of which was suicidal; 22 persons died by violence, 15 of whom committed suicide. In the same week the death-rate of Dresden was 19·6, of Berlin 19·8, of Hamburg 21·3, of Breslau 23·7, of Frankfort 25·2, and of Munich 33. Of the German cities Stettin had the lowest death-rate (16·3) and Chemnitz the highest (34·1).

News Items.

Professor Thiersch of Leipsic celebrated his seventieth birthday, and Professor Leyden of Berlin his sixtieth, on the 20th inst.

Professor Seitz of Munich died on Easter Monday, aged eighty. He was a medical writer of high repute, and one of the founders of the *Munich Medical Weekly*. A considerable number of his writings treat of epidemic diseases.

Professor Unverricht of Dorpat has been appointed head of the new hospital in Magdeburg.

Professor Delffs of Heidelberg celebrated his eightieth birthday on the 21st instant.

Professor Frommann of Jena died on the 22nd inst.

Berlin, April 26th.

Obituary.

CHARLES HAWKINS, F.R.C.S.ENG.

MR. CHARLES HAWKINS was born on May 29th, 1812, and died on April 4th last, having nearly completed his eightieth year. His father was a doctor of medicine, "of an old Monmouthshire family," says the *Tablet*, "and he was educated at Oscott, together with two brothers older than himself, one of whom died some years ago, and the other only recently, in the January of this year." The other brother, the late Mr. Robert Hawkins, a well-known barrister and an active governor of St. George's Hospital, was a Protestant. The family was in no way connected with that of the late Mr. Cæsar Hawkins. Mr. Charles Hawkins entered St. George's Hospital on Jan. 28th, 1829, as a perpetual pupil of Mr. Brodie, and was appointed house surgeon in 1836. His father had by this time settled in London, in Upper Brook-street. After twelve months spent in this post Mr. Hawkins entered into practice as a consulting surgeon, having become a Member of the College of Surgeons in 1837. His abilities and his high character had early attracted the notice and won the friendship of Brodie, and he began to assist that great surgeon in his practice. Brodie was then at the height of his fame, and had almost more patients than he could attend to. Mr. Hawkins used to say that for eight years Sir Benjamin Brodie never quitted London, except to fulfil some professional engagement. With such an introduction Mr. Hawkins saw and profited by the best surgical practice of the day, and he only required a hospital appointment to become one of the most accomplished surgeons of his time. As it was, he was an excellent practitioner, and was peculiarly well versed in those branches of surgery in which Brodie was pre-eminent. This was afterwards proved by his admirable article on Lithotrity in the "System of Surgery," edited by Mr. Holmes in 1864, and republished with the necessary additions in the second edition of that work in 1870. Any reader of this concise and judicious little treatise will recognise in it the hand of a master, and there are many contributions from Mr. Hawkins in the Pathological Transactions and other periodical publications on the same subject which show how profound and practical Mr. Hawkins' knowledge of this branch of surgery was. Amongst these we may mention a most interesting case of recto-vesical fistula in the male, in which a calculus formed round fæcal accumulation in the bladder, successfully treated by lithotrity, which was related in the forty-first and forty-second volumes of the Medical and Chirurgical Transactions.

Mr. Hawkins' chief title, however, to remembrance in the literature of surgery is as editor of Sir B. Brodie's works and of the autobiography of that great surgeon and philosopher. To this autobiography Mr. Hawkins prefixed a short notice of his life-long friend and master, which ends with these touching words: "When the Wellington despatches appeared a distinguished foreigner remarked, 'What a noble monument Colonel Gurwood has raised to the Duke—one more enduring than marble or brass.' The task of arranging such a monument to the best of friends and most indulgent of instructors has been to me a labour of love."

Mr. Hawkins remained Sir B. Brodie's nearest and most intimate friend during the whole of his long life, watched over him in his last illness, and attended him to the grave. This edition of Brodie's works is one of the classics of the profession, and will keep Mr. Hawkins' memory alive to the remotest time. Otherwise Mr. Hawkins did not contribute much to the literature of the profession, but to its institutions he gave a most active and untiring coöperation. He was an admirable man of business, clear-sighted in his aims, resolute in his purpose, and indefatigable in his pursuit of the essential object in view. He was a vigorous and respected Fellow of the Royal Medical and Chirurgical Society, of which at the time of his death he was about the oldest resident member, and which he had served in almost all its chief offices—secretary, treasurer, councillor, and vice-president. He took the liveliest interest in this great society, and advocated warmly the scheme for affiliating the minor societies to it. He served also for some years on the Council of the College of Surgeons, and favoured the reforms in the constitution of that body which have been always advocated by THE LANCET.

But it was to the hospital which he had chosen as his school that Mr. Charles Hawkins felt the most ardent attachment and rendered the most constant and the most efficient service. His own career there was indeed in one sense unsuccessful, for when he presented himself in the year 1843 to the governors as a candidate for the office of assistant-surgeon he was unsuccessful, although he had the powerful support of Sir Benjamin Brodie. The causes of that defeat were personal entirely. No one could doubt Mr. Hawkins' capacity as a surgeon; but his opponent, Mr. Henry C. Johnson, was overwhelmingly popular with the members of the school; and Mr. Hawkins' religious belief possibly alienated some of those who would otherwise have followed Brodie's lead. The election was marked by almost the excitement of a Parliamentary struggle, but its event was decisive. Mr. C. Hawkins never again sought the position, and on the next vacancy, in 1848, allowed his friend, Mr. Prescott Hewett, to be elected without opposition. Grave, however, as this disappointment must have been, it did not alienate Mr. Hawkins' affections from St. George's Hospital; on the contrary, he gave to its internal concerns and to its management a degree of attention and an amount of time which would have been impossible had he been performing the arduous duties of one of the surgical staff. He took the leading part in the government of this great hospital, and for many years exercised an almost unquestioned sway over it. The admirable country branch of St. George's Hospital which by the bequest of Mr. Morley was founded at Wimbledon was organised mainly by him, and he always supported the medical staff in resisting the conversion of this branch hospital into a

Digitized by Google

mere convalescent asylum. Mr. C Hawkins was for several years the acting treasurer of St. George's Hospital, and on his resignation of that office was elected vice-president. He knew the importance to the hospital of a good and flourishing medical school, and did all in his power to promote the success of that which had been rendered so illustrious by Brodie's connexion with it. The infirmities of age rendered his attendance at the hospital of late infrequent, but he was always received there when he came with affectionate respect.

Mr. Hawkins' services were highly valued by the numerous members of his own faith in London, and when in 1860 Cardinal Wiseman was seriously ill at Rome, Mr. Hawkins was sent for to attend him there, and received from Pope Pius IX. a gold medal in recognition of his services to the cardinal. It was not till a few years ago that Mr. Hawkins gave up his house in Savile-row and practically retired from active life, though he retained his appointment as inspector of anatomy, and was often to be met with at the Athenæum Club, where he loved to talk over old times with old friends. Few men indeed could talk better or were more interesting companions, and his health was good enough to enable him to enjoy society down to the end of last year, when he was attacked by bronchitis, which was aggravated by his imprudently, though conscientiously, persisting in the attempt to carry on the duties of his office. Confinement to the house and the watchful care of his medical friends had restored him to comfort and he began to take the air again. He had been chatting quietly with one of his St. George's Hospital friends on the last day of his life. Another coming in half an hour later found him sitting dead in his chair. He was never married, nor were his brothers, with the exception of the eldest, Mr. Henry M. Hawkins, who did not follow any profession. Mr. Hawkins was a man of vigorous character, strong in the assertion of his opinion, and ardent in his attempts to bring about what he thought right. Hence he encountered a good deal of opposition and controversy, and he was a formidable opponent; but he never bore any grudge against an honest adversary, and allowed the same freedom which he claimed for himself. His power of oratory was considerable—he spoke with clearness, force, and feeling,—and his talents for business were still greater. He had a cultivated and accurate taste, and would have filled with dignity and power an even higher position than he obtained. This, however, though below his merits, was sufficient to secure him the universal respect of the profession and the affection of a wide circle of intimate and attached friends.

ROYAL COLLEGE OF PHYSICIANS.

AT an ordinary meeting of the Comitia held on April 28th, Sir Andrew Clark, President, in the chair, the licence of the College was granted to one hundred and thirty-three candidates who had successfully passed the required examinations.

A communication was received from Mr. Garner, the Bedell, resigning his appointment at the end of twenty years' service, and on attaining the age of seventy. This resignation was accepted, and the question of pension was referred to the Finance Committee.

A formal communication was received from the Secretary of the Royal College of Surgeons. A short memorandum was received from the War Office, bearing upon the regulations for admission to the Army Medical Staff appointments.

The Solicitors to the College indicated that there was little probability of the case of the Royal College of Physicians *v.* the General Medical Council being reached before Whitsuntide, as it came late on the list. The College then proceeded to the election of Fellows.

A report from the Committee of Management relating to the various exemptions which are necessitated under the five years' curriculum was, after some discussion, referred back to the committee. A report from the By-laws Committee relating to the enactment, alteration, and repeal of sundry by-laws and regulations was proposed to be adopted for the first time.

The report of the examiners for the Murchison Scholarship announced that no candidate had been found worthy of the scholarship.

A report from the Council announced the nomination of Dr. Benjamin Arthur Whitelegge as Milroy Lecturer for 1893.

The quarterly report of the Finance Committee and the quarterly report of the examiners for the College Licence were received and adopted. The list of books presented during the last quarter was received, and, with a vote of thanks to the donors, the College adjourned.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At an ordinary meeting of the comitia held on April 28th, the following gentlemen were elected Fellows of the College:—

Donald William Charles Hood, M.D. Camb.; John Ebenezer Ranking, M.D. Oxon.; Harrington Sainsbury, M.D. Lond.; Thomas Colcott Fox, M.B. Lond.; William Arthur Foxwell, M.D. Camb, John Phillips, M.D. Camb.; Wm. Dobinson Halliburton, M.D. Lond.; Lauriston Elgie Shaw, M.D. Lond.; William Collier, M.D. Camb.; Hector Wm. Gavin Mackenzie, M.D. Camb.; Frederick Walker Mott, M.D. Lond.; James Reid, M.D. Aberd.

The following gentlemen were admitted as Members:—

John William Campbell, M.B Camb.; George Frederick Crooke, M.D. Edin.; Charles John Macalister, M.B Edin.; John Inglis Parsons, M.D. Durh.; William Japp Sinclair, M.D. Aberd.; Walter William Hunt Tate, M.B. Lond.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE. The following candidate obtained the Licence in Sanitary Science (L.S.Sc.) at the recent examination held at the College of Medicine, Newcastle-on-Tyne:—

Hall, Cornelius Scamp, M.R.C.S., L.S.A.

ROYAL UNIVERSITY OF IRELAND.—The following candidates (all of whom may present themselves for the further examination for Honours) have passed the Third Examination in Medicine of the University:—

Upper Pass Division.—Alfred G. Coldwell, Emily W. Dickson, W. Hanna, Patrick Joyce, William J. Maguire, and J. J. Wallace.

Pass.—Robert Allen, Charles Birmingham, James M. Browne, Joseph Clements, Thomas J. Connolly, Joseph A. Corbitt, Jas. De Blaquiere, Joseph Furey, Patrick Gerety, Michael Halfpenny, Purcell N. Lalor, Joseph P. Maguire, John Mathewson, Herbert C. Mooney, John Morrow, Alexander Park, John Reid, John Rusk, Michael J. Ryan, T. H. Scott, William Scott, John Shine, Maurice Sisk, and J. Young.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND: CONJOINT SCHEME.—The following candidates have passed the Second Professional Examination:—

C. A. Black, C. J. S. Cahill, H. G. F. Dawson, Marie Goodwin, J. W. Griffin, Christian Kapp, A. J. Kearney, E. Kennedy, H. E. W. Kinsella, W. P. Lappin, J. M. Longford, R. J. Maguire, J. P. Martin, H. McAvory, P. J. McHale, H. F. Nolan, P. Van Homrigh, and R. G. S. Whitla.

FOOTBALL CASUALTIES.—Last week, during a Rugby match at Warrington between Warrington and Leeds Parish Church clubs, a Warrington three-quarter back sustained a fracture of the clavicle. At Norbiton Park, on Good Friday, a similar accident happened in a club match to a player for the Gordon Club (Malden). On the 18th inst., during a match at New Mills, Derbyshire, a player broke his arm. On the 22nd inst. a youth playing in a game on the Woolwich-road, East Greenwich, fractured his leg.

LONDON POST-GRADUATE COURSE.—This course has now reached its eighth term, which will commence on May 2nd and end on June 25th. There are eleven distinct courses—on diseases of the chest, of the nervous system, of the skin, of children, of the eye, of the mind, of the throat, of women, and on sanitary science, bacteriology, and pathology. The lectures extend over eight weeks, and those who wish to enter for a shorter period can do so. All information can be obtained from the secretary, Dr. Fletcher Little, of 60, Welbeck-street, W.

PRESENTATIONS.—Dr. John Somerville, on his resigning the post of resident medical officer to the Union Infirmary, Firvale, Sheffield, which he has held for the past two years, has been presented by the nurses, the master, and matron, and other officers of the workhouse, with a handsome cake basket and reading lamp.—Dr. A. McNeill D'Evelyn of Ballymena has been presented by the members of the ambulance class, on the close of a course of lectures to the class under the St. John Ambulance Association, with a carriage clock.

Digitized by Google

MEASLES.—It is reported that the elementary schools in Loughborough, Lincolnshire, are to be closed for a month in consequence of an outbreak of measles.

MELBOURNE, VICTORIA.—John Fulton, M.D., C.M. Glasg., of Melbourne, has been appointed a justice of the peace.

THE discussion on Dr. Dickinson's paper on Renal Dropsy, which was read at the meeting of the Royal Medical and Chirurgical Society on Tuesday evening last, was adjourned to the next meeting on May 10th.

SMALL-POX.—A serious epidemic of small-pox prevails at the Pembroke Dock, Cardiff. Twenty-four cases are at present reported, and one death is said to have occurred. Certain streets in the town have been declared by the military authorities as "out of bounds," and a Wesleyan mission room and a Sunday school are closed. The authorities have not been able to prevent publicity being given to so formidable a disease. The first case was reported to the Local Government Board in a letter dated March 15th. The matter is exciting considerable local interest.

THE MANCHESTER CREMATORIUM.—The Duke of Westminster has shown his interest in this undertaking by contributing another £100 towards the building. A great effort is now being made to open the same freed from debt. The scheme includes a lodge, the ornamental laying out of the grounds, and an organ, and the total cost is expected to reach £7750, towards which a sum of about £5000 has already been subscribed. Further subscriptions will be received by Mr. J. Harvey Simpson, of 15, Princess-street, Manchester, the secretary to the company.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—Sir James Paget, president, took the chair at the quarterly court of directors of the Society, held on April 13th. Five deaths of members were reported, and only one new member was elected. Sixty-one widows and seventeen orphans applied for assistance, and it was resolved to distribute among them at the next court the sum of £1381. The deaths of three widows in receipt of grants were announced, and one orphan had, through age, ceased to be eligible for further assistance. The expenses of the quarter amounted to £58. It was resolved to recommend for election, at the annual general meeting, as vice-presidents Sir William Savory, Mr. Christopher Heath, and Mr. Aikin, to fill the vacancies caused by the deaths of Sir Prescott Hewett, Sir William Bowerman, and Mr. Lord; and as directors, Dr. Hare, Dr. John Williams, Mr. Warrington Haward, Mr. Alfred Cooper, Dr. Travers, and Mr. Lynch, in place of the six seniors who retire. It was agreed to hold the annual general meeting on Friday, May 20th, at 5 P.M.

BEQUESTS AND DONATIONS TO HOSPITALS.—The Clothworkers' Livery Company has made a donation of sixty guineas to the Royal Hospital for Diseases of the Chest, City-road.—The Goldsmiths' Livery Company has voted £250 to the London Fever Hospital, Liverpool-road.—The late Mr. Thomas Butlin of Camden-square, London, bequeathed £100 to the Great Northern Central Hospital, Caledonian-road.—The workmen of Sir W. G. Armstrong, Mitchell, and Co., at Elswick, Newcastle, contributed to the local medical charities £214 5*s.* 8*d* for the quarter ending the 31st ult., of which £149 8*s.* was apportioned to the Royal Infirmary.—By the death of Mrs. Sharp of Row, Dumbartonshire, the Victoria Infirmary at Glasgow succeeds to the whole estate of her first husband, Mr. Couper of Cathcart, Glasgow, estimated at from £30,000 to £40,000.—Mr. Richard Holtby of Filbert Grove, Nafferton, has given a donation of £100 to the Driffield Cottage Hospital.—Mrs. Bell of Newbridge has given £1000 towards the endowment of a trust at the Wolverhampton Eye Infirmary, in remembrance of her deceased brothers, Mr. Thomas Wilkinson Shaw and Mr. Edward D. Shaw of Wolverhampton.—The late Mr. Samuel Meriden of Compton-road, Wolverhampton, bequeathed £500 each to the Wolverhampton and Staffordshire General Hospital and the Wolverhampton Eye Infirmary. His will also stipulated that if the estate realised the amount, each institution was to receive an additional £1000.—The late Mr. John Bingham of Carolgate, Retford, bequeathed £400 to the Retford Dispensary and Cottage Hospital.

DEATH OF A CENTENARIAN.—The death of Mary Tesdale of Nunsbush, near Newborough, Northumberland, aged 102, was reported on the 26th inst., at the Hexham Board of Guardians. She was a native of Kirkhaugh, Cumberland, and leaves a number of descendants.

THE ROYAL COMMISSION ON VACCINATION.—We understand that the Royal Commission on Vaccination have issued an interim report, and that it has been delivered to Mr. Ritchie, the President of the Local Government Board. The report is stated to contain only the views of the Commissioners on the subject of cumulative fines for non-compliance with the vaccination laws.

LAMBETH AND THE PUBLIC HEALTH (LONDON) ACT.—Last week this vestry resumed the discussion of the report of the Sewers and Sanitary Committee. The committee, in accordance with a suggestion from the medical officer of health, submitted several proposals having in view a more adequate and efficient sanitary administration of the parish. There was a prolonged discussion, the ultimate result being that the subject was referred back again to the committee, with instructions to prepare, in concert with the board of guardians, a scheme excluding a house-to-house inspection.

FOOT-AND-MOUTH DISEASE IN LONDON.—The Board of Agriculture have notified their inspectors that, as no outbreaks of foot-and-mouth disease have been reported in London during the past three weeks, it is proposed for the present to discontinue the daily inspections until further notice. These inspections were ordered when the disease first became known, and, after being discontinued from March 6th until March 10th, were resumed in consequence of further outbreaks. It is now confidently hoped that the complaint has been effectually stamped out, and that some of the restrictions placed upon the movement of cattle may be removed at an early date.

MEDICAL NOTES IN PARLIAMENT.

A London Teaching University.

IN the House of Commons on the 25th inst., Sir A. Rollit asked the First Lord of the Treasury whether he was able to state the terms of the reference to a Royal Commission of the question of University education in London, and the names of the Commissioners. Mr. Bartley had a similar question on the paper. Mr. Balfour: 1. The terms of the reference (as received at the Home Office from the Privy Council Office) are:—"We, taking the premisses into consideration, do authorise the said Commissioners to consider and, if they think fit, alter and amend and extend the proposed charter remitted in compliance" with an address of the House of Commons, "so as to form and report to us a scheme for the establishment under charter of an efficient Teaching University for London." 2. The names of the Royal Commissioners are as follows:—Earl Cowper, K.G. (chairman), Lord Reay, G.C.S.I., G.C.I.E., Bishop Barry, the Right Hon. Sir Lyon Playfair, K.C.B., LL.D., Sir William Scovell Savory, Sir George Murray Humphry, M.D., LL.D., Mr. George G. Ramsay, LL.D., Rev. Canon Browne, B.D., Mr. Henry Sidgwick, Litt.D., Mr. John Scott Burdon Sanderson, M.A., Mr. James Anstie, Q.C., Mr. Ralph Charlton Palmer, and Mr. Gerald Henry Rendall, M.A.—Dr. Farquharson asked why the representation of the medical profession was restricted so exclusively to the surgical side. Would the right hon. gentleman take into consideration the desirableness of appointing someone to represent the general practitioners of the United Kingdom.—Mr. Balfour: I will inquire of my noble friend, who is responsible for the submission of this list to her Majesty. But I think the hon. gentleman will find that the subject of increasing the number of Commissioners is a difficult one. I believe Sir G. Humphry is not merely a surgeon, but is also a doctor of medicine.—On Thursday, in reply to Dr. Farquharson, the First Lord of the Treasury said the Government were not disposed to add to the number of the Commissioners. It would not therefore be possible to add a representative of the general medical practitioners.

Plumbers' Registration Bill.

The House went into Committee on this Bill, but progress was immediately reported.

New Bill.

Leave was given to bring in the following Bill, which was read a first time:—The Lord Advocate,—Bill to amend the Housing of the Working Classes Act, 1890, as to Scotland.

Naval Medical Officers.

Dr. Tanner has given notice that he will inquire of the First Lord of the Admiralty whether any and if so what steps have been taken to carry out the promise given by the First Lord of the Treasury that medical officers in the navy will be granted permission to attend, while on full pay, the medical schools in Great Britain, after having been certain periods afloat.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ARKLE, CHARLES, M.D., M.R.C.P., has been appointed Pathologist and Curator of Museum at Charing-cross Hospital.

ATTERBURY, WALTER, M.D. Irel., M.R.C.S., has been appointed Government Medical Officer and Vaccinator for the District of Hillgrove, New South Wales.

BAILEY, T. R., M.D., C.M. Edin., has been reappointed Medical Officer of Health for Bilston.

BARRATT, J. O. W., B.Sc., M.B. Lond., F.R.C.S., has been appointed Visiting Physician to the Birmingham Workhouse Infirmary.

BARTLETT, RALPH C., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the Teignmouth, Dawlish, and Newton Infirmary.

BRANNIGAN, H. C., M.D., M.Ch. Irel., L.R.C.P., L.R.C.S. Edin., has been appointed a Surgeon to the Queensland (Land) Defence Force.

BROWN, JOHN G., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer of the Bowen Hospital, Queensland, vice De Vis, deceased.

CARTER, A. H., M.D. Lond., F.R.C.P., M.R.C.S., has been appointed Visiting Physician to the Birmingham Workhouse Infirmary.

CHADWICK, C. M., M.D. Oxon., M.R.C.P. Lond., M.R.C.S., has been appointed Senior Honorary Assistant Physician to the Leeds General Infirmary.

CROWTHER, THOS., M.D., M.R.C.S., has been appointed Medical Officer of Health for the Warley Urban Sanitary District of the Halifax Union.

CUMINE, J. M., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer of Health for the Tunstall Urban Sanitary District of the Wolstanton and Burslem Union.

EDDIE, ROBT., M.B., C.M. Aberd., has been appointed Government Medical Officer and Vaccinator for the District of Bombala, New South Wales.

EDWARDS, ARNOLD J., M.B., B.Ch. (Vict.), has been appointed House Surgeon to the Manchester Southern Hospital and the Manchester Maternity Hospital.

GANGEE, L. P., L.R.C.P. Lond., M.R.C.S., has been appointed Obstetric and Ophthalmic House Surgeon to the Queen's Hospital, Birmingham.

GIBB, WM., L.R.C.P., L.R.C.S. Edin., has been appointed a Public Vaccinator in South Australia.

GRAY, A. C. E., M.B., C.M. Edin., has been appointed House Surgeon to the Royal Maternity and Simpson Memorial Hospital, Edinburgh, vice Fraser.

GRIFFITH, THOS. W., M.D. Aberd., C.M., has been appointed Honorary Assistant Physician to the Leeds General Infirmary.

HAWKINS, W. R. T., M.R.C.S., has been appointed Medical Officer for the Third Sanitary District of the Barton Regis Union.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

We cannot undertake to return MSS. not used.

SUPERSTITION AND DISEASE.

EVEN among the intelligent and comparatively well educated Highlanders the superstitions which have been handed down from remote ages have many ardent believers. Superstition regarding the treatment of disease always dies hard. This receives striking corroboration in the ancient belief regarding king's evil. In connexion with this tradition the seventh son's seventh son was also credited with miraculous powers, and the following extract from a letter, written apparently by a person of some intelligence, which appeared in the *Glasgow Herald*, illustrates the tenacity of popular error. The writer says:—

"With us, in Scotland, it is well known and universally believed in, but with a difference. The last of seven sons born—no daughter intervening—is considered a natural doctor, and should not be brought up to any other profession, but has never, to my knowledge at least, been credited with the possession of extraordinary healing power; they were clever and successful doctors, but nothing beyond. It is the seventh son of a seventh son who is gifted with the marvellous power of healing by touch. Touching for evil by kings is a mere superstition, but that a healing power is actually possessed by 'Septimus Septimi' is an assured fact, and there is no secrecy or reservation whatever observed here with regard to its application. I had a servant once—Mary Keogh—whose father, being a seventh son's son, possessed this gift. Numbers of people came to him, and amongst many other things she told me of a woman who brought her child—a terribly diseased little boy—entreating her father to cure him, and Mr. Keogh consented. He made a slight cut on the inside of his own leg, just deep enough to draw blood; this blood he applied to the sores, whether once or oftener I cannot say, and the child recovered. 'And you may see him, mem, any day you please, as fine a young man as walks the streets of Dublin!' It is well known, and generally believed in the west of Ireland, that the blood of three Irish families—the Welches, *Keoghs*, and Cahills—is the 'finest thing in life' for the cure of any cutaneous disease—rose (i.e., erysipelas), wildfire, shingles, &c.; and I imagine that it may have been to him, as a *Keogh* the woman came, and with no reference to his birthright, of which it is not only possible, but probable, she may never have heard. Either way, the child *was* cured. I visited this person several times, intending to question him, but found him so ill that I did not like to do so, and he died on Jan. 17th, 1888. He had ten daughters, but only one son, and has left no inheritor of his marvellous gift."

Mr. Alfred E. Ward.—The particulars asked for are given in our present issue, p. 998.

M.D., B.S.—Registration alone gives validity to certificates.

ADVERTISEMENT THROUGH HOSPITALS.

THE following is from the *Birmingham Daily Mail* of April 16th. The personal element in the advertisement is very marked, Mr. March's name and title occupying a well-leaded space. We should like to see a prompt and complete disclaimer from him of any responsibility in the matter:—

"*Notices to Patients.*—Mr. March, F.R.C.S. Eng., having been appointed Assistant-Surgeon to this Hospital, will see patients at 11.30 on Wednesdays and Saturdays, commencing Saturday, 23rd current.—By order of the Committee, Geo. A. Panton, Hon. Sec. Birmingham and Midland Ear and Throat Hospital, 109, Edmund-street, 8th April, 1892."

Mr. Samuel Davey.—The appointment of coroner rests, we believe, with the County Council, which controls the Newington district; but full information will, no doubt, be given in the leading daily papers. Our correspondent should lose no time in sending in his application with testimonials.

Major Fraser should consult his usual medical attendant.

EPISTAXIS.

To the Editors of THE LANCET.

SIRS,—*Apropos* of the subject of epistaxis, towards the successful treatment of which your correspondent, Dr. Philip, has made so valuable a contribution, may I ask the following question, in the hope of an answer from one of your many readers?

What is the *rationale* of instructing a patient suffering from epistaxis (as all authorities seem to do) to assume the recumbent position and to raise the arms above the head? The object aimed at, I take it, is to divert or decrease the flow of blood which passes to the nose; but to raise the arms above the head is surely to render the passage of blood by the subclavians more difficult, and therefore to leave the current free to choose the by so much easier passage by the carotids, and to lower the head is to assist the flow of blood thereto, and therefore distinctly to encourage just what we wish to avoid. If it be answered that by raising the arms above the head we discourage, by rendering more difficult, the passage of blood through the subclavians and the carotids together (though I think that the effect upon them must be, as I have argued above, antagonistic rather than coöperative), then surely we ought not, unless it be an impending syncope that we are afraid of, to minimise the effects of this salutary coöperation by assisting the blood to flow more easily, certainly through the carotids, but not so certainly through the subclavians, as we do by enforcing the recumbent position. Though one or other of these methods of treatment may be right, it appears to me that they cannot both be. Can anyone reconcile or justify them? I am, Sirs, yours faithfully,

Tulse-hill, S.W., April, 1892. A. B. STEVENS, M.B.

"SPRAY PRODUCERS WITH CHECK ACTION."

To the Editors of THE LANCET.

SIRS,—In connexion with the correspondence which has appeared in your columns on the above subject I should like to observe that I introduced a spray producer which was figured and described in THE LANCET of June 13th, 1885, the check action of which was secured by having a small aperture about half way along the outer portion of the air-pipe. With the left hand holding the bottle, the aperture was so placed that the left thumb could easily cover it; and as soon as it was found necessary to close the spraying the thumb was removed, allowing all the superabundant air to escape through the opening, instead of passing through the jet. It was originally designed for the purpose of using with cocaine solutions, to prevent waste when the alkaloid was expensive; but the apparatus can be employed for any purpose where a spray is indicated. I am, Sirs, yours truly,

Welbeck-street, W., April, 1892. H. PERCY DUNN.

To the Editors of THE LANCET.

SIRS,—We have only just read Mr. W. R. H. Stewart's letter in THE LANCET of the 16th inst. We beg to state that we had not seen and were not aware that a similar instrument had been made before, or we certainly should not have asked you to notice it.

We are, Sirs, yours respectfully,

Moorgate-street, April 27th, 1892. F. WALTERS & Co.

A DISCLAIMER.

To the Editors of THE LANCET.

SIRS,—My attention having been drawn to a personal notice published by a local paper, and reproduced by THE LANCET under the heading "Puffing of Medical Men by the Lay Press," I wish to state hereby most emphatically that I have had nothing whatever to do with it.

I am, Sirs, your obedient servant,

Abbey-road, N.W., April 24th, 1892. A. GASTER, M.D., M.R.C.P.

"MEDICAL PRACTICE IN SOUTH CALIFORNIA."

To the Editors of THE LANCET.

SIRS,—If "Quercus Ilex" will communicate with me I can give him the information he requires, having passed last summer in Southern California.—I am, Sirs, your obedient servant,

G. C. BRIGHT, M.D.Oxon., F.R.C.P.Lond.

Chalet Magali, Cannes, France, April 26th, 1892.

Medical Diary for the ensuing Week.

Monday, May 2.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Tuesday, Wednesday, Friday, and Saturday at the same hour.
ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations daily at 10 A.M.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.
UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.
LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital: 1 P.M., Mr. R. Marcus Gunn: External Examination of the Eye.—Great Northern Central Hospital: 8 P.M., Dr. Galloway: Heart, Valvular Lesions.—Parkes Museum (Margaret-st., W.): 4 P.M., Dr. A. Wynter Blyth: House Drainage.
ROYAL INSTITUTION.—5 P.M. Annual Meeting.
ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-sq., W.C.).—8 P.M. Mr. S. A. Coxon: Cystic Sarcoma of Superior Maxilla—Sir Wm. Mac Cormac will kindly speak (patient in attendance).—Mr. Stanley Boyd: Suggestion of a plan for preventing Lateral Displacement of the Chin after Removal of a portion of the Lower Jaw (with case).—Mr. Stanley Boyd: A case of Removal of one Condyle of the Lower Jaw for Closure of the Jaws (patient shown).—Mr. E. W. Roughton: An Ivory Exostosis removed from the Lower Jaw.
SOCIETY OF ARTS.—8 P.M. Mr. Percy F. Frankland: Recent Bacteriological and Chemical Research in connexion with the Fermentation Industries.
MEDICAL SOCIETY OF LONDON.—Annual Conversazione. Oration at 8.30 P.M. by Sir Jas. Crichton Browne, F.R.S., on "Sex in Education."

Tuesday, May 3.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.; Fridays and Saturdays at the same hour.
GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same day, 2 P.M.
LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars: 4 P.M., Mr. Jonathan Hutchinson: The more rare forms of Lupus.—Bethlem Hospital: 2 P.M., Dr. Percy Smith: Hysteria, Delirious Mania.
ROYAL INSTITUTION.—3 P.M. Professor Bonney: The Sculpturing of Britain—its Later Stages. (The Tyndall Lectures.)
PATHOLOGICAL SOCIETY OF LONDON.—Mr. C. B. Lockwood: Polypus of Small Intestine associated with Intussusception.—Mr. E. W. Willett: Fibroma of Dura Mater depressing the Rolandic region of the Brain without Symptoms.—Dr. E. T. Wynne: Hæmatoma Auris.—Dr. Arnold Chaplin: Two Hearts with Stenosis of Mitral and Tricuspid Orifices.—Dr. W. Edmunds: Aneurysm of Internal Carotid Artery. Dr. H. P. Hawkins: General Arteritis in a Child, with narrowing of the Abdominal Aorta.—Mr. E. H. Fenwick: Primary Malignant Growth of Corpora Cavernosa.—Mr. S. G. Shattock: Paradidymal Cyst.—Mr. W. W. H. Tate: Malformation of Heart. Card Specimens:—Dr. E. T. Wynne: Sarcoma of Gall-bladder and Genital Organs.—Dr. H. D. Rolleston: Guinea-worm in Subcutaneous Tissue of Calf twenty-eight years.—Mr. Alban Doran: Adeno-sarcoma of Breast weighing 8 lb.—Mr. W. F. Haslam: Sebaceous Horn.—Mr. S. G. Shattock: Columnar-celled Carcinoma of Male Breast.

Wednesday, May 4.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1.30 P.M.; Saturdays, 2 P.M. Obstetrical Operations, Thursdays, 2 P.M.
CHARING-CROSS HOSTITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.30 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.
LONDON POST-GRADUATE COURSE.—Hospital for Consumption, Brompton: 4 P.M., Dr. C. Theodore Williams: The Diagnosis of Pulmonary Tuberculosis.—Royal London Ophthalmic Hospital: 8 P.M., Mr. A. Quarry Silcock: Glaucoma.
OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Mr. Alban Doran, Dr. Cullingworth, Dr. John Phillips, and others. Dr. Lewers: Six Cases of Craniotomy with Remarks on the Relative Position of Craniotomy and Cæsarean Section.—Dr. W. S. A. Griffith: A case of Galactorrhœa during a first Pregnancy.
SOCIETY OF ARTS.—8 P.M. Mr. James N. Shoolbred: The Bradford Corporation Electricity Supply.

Thursday, May 5.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.
LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Great Ormond-st.: 4 P.M., Mr. Edmund Owen: Selected Surgical Cases from the Wards.—National Hospital for the Paralysed and Epileptic: 2 P.M., Dr. Charlton Bastian: Aphasia and other Speech Defects.—London Throat Hospital, Gt. Portland-st.: 8 P.M., Mr. W. R. H. Stewart: The Examination of Ear Cases.
ROYAL INSTITUTION.—3 P.M. Professor Dewar: The Chemistry of Gases.
ROYAL COLLEGE OF SURGEONS.—4 P.M. Dr. G. S. Woodhead: Cancer and Cancerous Diseases. (Morton Lecture.)
OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8.30 P.M. Patients and Card Specimens at 8 P.M. Mr. Kingdon: Fatal Disease of Infancy, with Symmetrical Changes at the Macula Lutea.—Mr. Higgens: Spontaneous Cure of Cataract.—Mr. Spicer: Vasculitis in Inherited Syphilis.—Mr. Sydney Stephenson: Scarring of the Conjunctiva from Ophthalmia Neonatorum.—Mr. Story: Detachment of the Choroidea.—Mr. Wherry: Orbital Neuroma (card).—Mr. Doyne: (1) Fragment of Steel embedded in Iris for twelve years; (2) Plugging of Arteria Centralis Retinæ; (3) Epithelioma (?) of Cornea (cards).

Friday, May 6.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
LONDON POST-GRADUATE COURSE.—Hospital for Consumption, Brompton: 4 P.M., Dr. C. Theodore Williams: Pulmonary Cavities.—Bacteriological Laboratory, King's College: 11 A.M. to 1 P.M., Professor Crookshank: The Microscope (Types of Bacteria).—Charing-cross Medical School: 8 P.M., Dr. Herman: Amenorrhœa.
WEST KENT MEDICO-CHIRURGICAL SOCIETY (Greenwich).—Adjourned Discussion on Influenza.
WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital).—8 P.M. Specimens:—Dr. A. Clemow: Calcification of Spleen.—Mr. W. P. Mallam: Obstructed Gall-duct. Paper:—Dr. Handfield Jones: A Clinical Study of the Causation and Treatment of Cervical Dysmenorrhœa.
ROYAL INSTITUTION.—9 P.M. Captain Abney: The Sensitiveness of the Eye to Light and Colour.

Saturday, May 7.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.
LONDON POST-GRADUATE COURSE.—Bethlem Hospital: 11 A.M., Dr. Percy Smith: Mania.
ROYAL INSTITUTION.—3 P.M. Mr. E. Dannreuther: J. S. Bach's Chamber Music (with many Musical Illustrations).

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 12 6 | Six Months £0 16 3

TO THE CONTINENT, COLONIES, UNITED STATES, INDIA, CHINA, AND ALL PLACES ABROAD ..... One Year 1 14 8

*** In consequence of the new postal arrangements, the Annual Subscription for India, China, and all foreign countries will now be reduced to £1 14s. 8d., instead of £1 16s. 10d. as formerly.

Post Office Orders and Cheques should be addressed to The Publisher, THE LANCET Office, 423, Strand, London, and crossed "London and Westminster Bank, St. James's-square."

ADVERTISING.

Books and Publications (seven lines and under)		£0	5 0
Official and General Announcements		0	5 0
Trade and Miscellaneous Advertisements		0	4 6
	Every additional Line	0	0 6
Front Page	per Line	0	1 0
Quarter Page		1	10 0
Half a Page		2	15 0
An Entire Page		5	5 0

The Publisher cannot hold himself responsible for the return of testimonials &c. sent to the office in reply to advertisements; copies only should be forwarded.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

GLYCERINUM PEPTICUM.
(FAIRCHILD.)

This Glycerine extract of the peptic ferment possesses every requisite of a concentrated solution of pepsin. It is highly active, uniform and stable, devoid of objectionable odour or taste, is freely miscible without precipitation or cloudiness with all proper menstrua or media, is notably free from all disagreeable qualities and characteristics of peptone solutions. It contains no alcohol or antiseptics other than glycerine of the purest quality.

Glycerine possesses peculiar value as a vehicle for pepsin, it being the only substance known which is at once both a powerful solvent and a preservative of the ferments of the gastric juice. For this reason, glycerine extracts of pepsin have been recommended and employed in experimental work by physiological chemists.

The properties and value of pepsin are so well known that the advantages of a pure glycerine extract of this ferment will be well understood by both pharmacists and physicians.

Glycerinum Pepticum (Fairchild) possesses every desiderata, both from a pharmaceutical and medicinal standpoint.

Twelve minims will be found equivalent in activity to one grain of the best pure pepsin in a dry form that is to be found in the market. It will be found, upon comparative test, of much greater strength than any fluid preparation of pepsin known.

It mixes freely, without precipitation or cloudiness, with all clear liquids with which pepsin is or should be employed.

Pharmacists will appreciate the facility with which the usual fluid preparations of pepsin may, by means of the Glycerinum Pepticum, be quickly and economically prepared, as there is no loss by filtration. It is agreeable to take, and may be mixed with pure water, wine, or any of the usual vehicles.

Glycerinum Pepticum supplied to the Medical Profession in 4-oz. bottles, at 1/10 each. Retail, 2/6 each.

THE IDEAL NUTRITIVE BEVERAGE.

ESSENTIA MALTI (KEPLER).

WE have recently introduced a new food agent and aid to the digestion of farinaceous substances under the above name. This preparation is manufactured by a modification of the KEPLER process for making the well-known **Kepler Extract of Malt.**

The KEPLER ESSENCE OF MALT contains a large amount of **Diastase** and natural mineral phosphates, and a considerable amount of tissue-forming substances. *The immense superiority of this preparation over ale and stout* is at once apparent when the process of manufacture is considered in detail. In making ale and stout the carbo-hydrates (so valuable as nutrient material) and the diastase (a most important principle of Malt, being of special service in errors of nutrition accompanied by digestive derangement) are sacrificed for the production of alcohol; whereas *in the KEPLER ESSENCE OF MALT these are carefully preserved intact.* This Essence is therefore an ideal aid to digestion and nutrient agent. **A wine-glassful of the Kepler Essence of Malt contains more elements of nutrition than a pint of the finest alimental stout.**

The flavour of the ESSENCE OF MALT is delicious. It is admirable as a table beverage when diluted with aërated water, and as an addition to milk for infant and invalid dieting; for it sweetens it and facilitates its prompt and perfect digestion. The Essence may be taken in coffee, gruel, aërated or plain water, wine, or mixed with any farinaceous pudding. As an addition to the food for young children its value cannot be over-estimated. It increases the value of all farinaceous food, and prevents the starch in such food, and large clots of curd in milk diet, overtaxing the power of the digestive functions.

For Lactating Women the ESSENCE OF MALT (KEPLER) contains many desirable properties; it quickly increases the flow and enriches the quality of the milk. It is serviceable as a laxative for young children, especially when constipation depends upon the defective digestion of starch. As a food beverage, it cannot fail to be productive of the highest benefit, either in **acute disease** or during **convalescence**; in fact, wherever there is defective nutrition, the KEPLER ESSENCE OF MALT is useful as a nutritive food.

As a Linctus, the Essence of Malt food, swallowed slowly, in the troublesome, dry, laryngeal cough, and the hacking cough of puberty or consumption, is pleasantly grateful and soothing, aids digestion, and builds up the tissues.

The KEPLER ESSENCE OF MALT is supplied to the profession in champagne pints at 1s. 2d. each. Retail 1s. 6d. each.

BURROUGHS, WELLCOME, & CO., SNOW HILL BUILDINGS, LONDON, E.C.

A Specimen will be sent free to any Medical Man on request.

An Oration
ON
SEX IN EDUCATION.

Delivered at the Medical Society of London on May 2nd, 1892,

BY SIR JAMES CRICHTON-BROWNE, M.D., LL.D., F.R.S.,
LORD CHANCELLOR'S VISITOR.

MR. PRESIDENT AND GENTLEMEN,—When that eccentric father of a family of geniuses, the late Rev. Mr. Brontë, desiring that his children should speak freely and without timidity, put them behind a mask and questioned them on various subjects, he was told by his son Branwell, then seven years old, in answer to one of his interrogations, that the best way of knowing the difference between the intellects of men and women is by considering the differences between them as to their bodies. That deliverance of the precocious boy seemed to his father at the time a wise saying, worthy of being recorded, and I daresay it seems the same to us as medical men to-day; but it is incontestable that there are now large numbers of cultivated persons to whom it must sound as foolishness, and a mere infantile echo of a barbarous prejudice. Their reply to Mr. Brontë's question would be that it is impossible to distinguish between the intellects of men and women, as there is no difference between them. Bodily differences cannot be overlooked; they are still obtrusive and are admitted. Certain emotional differences are perhaps conceded; but, as regards intellect, we are told that in its pure atmosphere all gross sexual characteristics disappear. The intellect of woman, it is maintained, except in so far as it has been enfeebled by long ages of subjection, is as good as that of man, if not better. And even where this extreme view is not theoretically held, it is often practically acted on, for those who admit that there are certain differences between the male and female intellect still not rarely advocate the coequal and coördinate employment of men and women in all intellectual exercises and pursuits. There is a growing tendency around us to ignore intellectual distinctions between the sexes, to assimilate the education of girls to that of boys, to throw men and women into industrial competition in every walk of life, and to make them compeers in social intercourse and political privileges. And as to my thinking this tendency is unphysiological, and likely, if indulged, to lead to some unfortunate results, I seize the opportunity which, by your kindness, I enjoy this evening to vindicate the wisdom of Master Branwell Brontë, to insist that there are differences between the intellects of men and women, and that these are best understood by a study of the differences in their bodies, and to suggest that forgetfulness of these differences is already doing injury in one department of education—I mean the high-school education of girls.

Now, to catalogue in the briefest way the bodily differences between men and women which underlie their intellectual disparities would be exhaust the time at my disposal. They are universal and intimate, and involve every organ and tissue. They extend from cuticular appendages to the marrow of the bones, from the crown of the head—for, according to Broca, the female cranium is less elevated than that of the male—to the sole of the foot; for, according to Delaunay, woman has a plantar arch flatter than that of men, which perhaps accounts for her partiality for high-heeled boots. I shall not attempt such an extensive anatomical survey. My present purpose will be served by directing your attention to certain sexual differences in one bodily organ—the brain,—differences which have been greatly lost sight of, which much require further investigation, but which are of peculiar significance in connexion with intellectual manifestations.

And first amongst cerebral differences between the sexes I would refer to mass and weight, qualities with which one almost insensibly associates power and strength. Now, it is a matter of common observation that women have smaller heads than men, and it is a matter of scientific observation that in all peoples and races, without exception, the absolute weight of the entire brain is on the average greater in men than in women, though of course individual women do sometimes possess larger and heavier brains than individual men. But it is also a matter of scientific observation that there is a correlation between brain weight and stature, and, laying hold of this fact, the advocates of women's rights and mights have argued that the deficiency in her brain weight when compared with that of man is no more than is to be accounted for by her fewer inches. But this position is quite untenable. I do not know a trustworthy standard of the brain weights of healthy natives of this country to which to appeal, but I can submit to you a table showing the results of the weighing of the brains of a large number of insane persons, all English, Scotch, or Irish, but mostly English, which, in this relation, is absolutely reliable. In this table are summed up the brain weights

TABLE I.—*Brain Weight.*

Sexes.	Average weight of brain.		Average height.			Excess of male over female brain wght.		Excess of male brain weight after allowance for height.	
	Grms.	Ounces.	Metres.	Feet.	Inches.	Grms.	Ounces.	Grms.	Ounces.
945 Males ..	1350·54	47·64	1·702	5	7	127·68	4·50	29·71	1·05
655 Females	1222·86	43·14	1·575	5	2	—	—	—	—

of 1600 persons—945 males and 655 females—ranging from ten to eighty years of age, the weighing of the brain having been in each case conducted by myself or under my own supervision. You will observe that the brains of males exceeded those of females in weight by 127·68 grammes (or 4·50 ounces) on the average; and that, after allowing for differences of stature—taking 5 ft. 7 in. as the average male height, and 5 ft. 2 in. as the average female height,—there is still an excess of brain weight of 29·71 grammes (or 1·05 oz.) in favour of the male. This is a very substantial difference, and if we recollect that the brain of the ant, of the mental powers of which Sir John Lubbock has spoken in such complimentary terms, declaring that they differ from those of man not so much in kind as in degree, is of the size of a pin point, we shall realise that an extra ounce of brain matter within the human cranium may imply an enormous mental difference. But it is certain that the actual difference in brain weight between healthy English men and English women is much more than one ounce. My table, as I have told you, deals with lunatics dying in asylums, and amongst them organic diseases of the brain, involving loss of substance, are at least twice as frequent in men as they are in women. Women are oftener attacked by insanity, but men oftener die of it. General paralysis of the insane, atrophy and softening of the brain, senile dementia, and other diseases causing wasting of the convolutions, are far more fatal to men than to women, who, when they die in asylums, succumb most frequently to bodily diseases which do not seriously interfere with the nutrition of the brain. And so it comes about that of the brains weighed in the post-mortem theatre of an asylum, those of men are on the average much more water-logged and reduced below their normal bulk than those of women. The effect of organic diseases and the atrophic changes they induce in lowering, in my tables, what is the normal difference between the male and female brain may be statistically demonstrated from these tables themselves. It is from thirty to fifty years of age that the mortality from general paralysis, which destroys four men to one woman, and from other fatal forms of organic brain disease, preferentially attacking men, except, of course, senile dementia, almost exclusively occurs, and it is in this section of life that the sex difference in brain weight in my tables falls to the lowest point at the very time when, under normal circumstances, it ought to be greatest. The average excess of weight in the male as compared with the female brain from thirty to fifty years of age in my tables was 123·5 grammes, or 4·37 ounces, while from twenty to thirty years, when deaths from organic brain disease are rare, it was 169·9 grammes, or 6·01 ounces. All available evidence points to the conclusion that the

Digitized by Google

male brain exceeds the female brain in weight in this country to an even greater degree than has been hitherto supposed. And that the smaller size of the female brain is a fundamental sexual distinction, and is not to be accounted for by the hypothesis that environment, educational advantages, and habits of life, acting through a long series of generations, have stimulated the growth of the cerebrum in one sex more than in the other, is made clear by the fact that the same differences in brain weight between men and women has been found in savage races. And not only is the male brain heavier than that of the female, but it has a wider range of variation in weight. The very big brains and the very small brains are encountered, just as are geniuses and idiots, giants and dwarfs, more frequently amongst men than amongst women.

I have said that an extra ounce of brain matter within the cranium might involve an enormous mental difference. It would do this were it generally and equally distributed, and it would do so in a still more striking manner were it localised in a certain region of the cerebrum; and there are grounds for believing that there is a difference in the balance of parts in the male and female brains respectively, and this difference I adduce as the second sexual distinction between them. Broca, no mean authority, has declared that the occipital lobes are more voluminous in the female than in the male, and my own observations, published in *Brain* in 1880, confirm, as far as they go, his conclusion, and show that while the frontal lobes are equally developed in both sexes, the parietal lobes corresponding roughly with the motor area of Ferrier are larger in the male than in the female, and the occipital lobes, certainly sensory in their functions, are larger in the female than the male.

The third brain difference between the sexes to which I would allude is one of convolutial arrangement which cannot yet be accurately defined, but which the examination of a series of photographs of brains of men and women, which have been stripped of their membranes, pretty clearly reveals. The brains of women, like their bodies generally, are, upon the whole, more symmetrical than those of men. The difference which I have found in the weight of the hemispheres points to this conclusion, for in males the right hemisphere exceeds the left in weight by 3·7 grammes, and in females by only 2·1 grammes; but pathological considerations as to the regional distribution of wasting in organic diseases forbid me to attach too much importance to this observation, and I prefer to trust to mere ocular inspection, which will, I think, bring home to anyone who diligently uses it the superior symmetry of the female brain, due to its comparative poverty in secondary gyri.

It is in the internal structure of the brain, in the depth and arrangement of its grey matter, in the size, form, and connexions of the cortical cells in different areas, that the most essential differences between the male and female brain in all probability reside; but the internal structure of the brain in this relation is as yet uninvestigated. I may mention to you, however, one fact which suggests some difference in the constitution of the grey matter of the brain in the two. During a very laborious inquiry into the specific gravity of the grey matter of every gyrus of the brain, which I carried out some years ago, I succeeded in obtaining three standard brains of perfectly healthy adults—two men and one woman—killed in accidents, and in these I found that while the specific gravity of the medullary substance of the brain was alike in all in each region—namely, 1044—that of the grey matter varied remarkably. To take the frontal convolutions as an example in the one male, the grey matter of these had a specific gravity of 1037, in the other of 1036, but in the female its specific gravity was only 1034. And not only in the frontal region, but in every convolution the specific gravity of the grey matter was lower in the female than in the male. I do not lay any great stress on the observation of a single case, but in several cases of death during acute insanity, which I examined, in which there had not been time for the establishment of degenerative changes, the specific gravity of the grey matter in every lobe of the brain was lower in the female than in the male, while the specific gravity of the white matter always closely corresponded in the two. In all degenerative diseases of the brain, and especially in senile decay, there is a reduction in the specific gravity of the grey matter, which sometimes falls as low as 1028, in the frontal region; and the fact—if it be a fact—that the grey matter in the female brain is of less density than that in the male brain must mean that it is a less highly nourished and developed tissue.

And there is still another brain difference between men and women which I must submit to you, and that a very momentous one—namely, vascular supply. During the last four years Dr. Sydney Martin and I have, as opportunity has offered, carried on an inquiry as to the size of the great arteries that supply the brain. The details of our observations, which have been conducted by Dr. Sydney Martin with scrupulous care, and by new methods insuring, I believe, great accuracy of measurement, will be communicated to the Royal Society when they are complete; but I may mention now one or two of the results at which we have arrived. We have found that the diameters of the internal carotid and vertebral arteries, taken together, are slightly greater in the male than in the female. Their combined diameter is 8·2 millimetres in the male and 8·0 millimetres in the female; but when the difference in weight of the male and female brain is taken into account, it is found that in proportion to brain weight their diameter is greater in the female than in the male, and so it appears that upon the whole the female brain receives a larger supply of blood in proportion to its mass than does the male brain; but of course it is to be remembered that the blood going to the female brain is poorer in quality than that going to the male brain, and contains only 4,500,000 corpuscles to the cubic millimetre, instead of 5,000,000 in the case of the male. But Dr. Sydney Martin and I have found further that the internal carotid and vertebral arteries, when measured separately, display a marked difference in calibre in male and female brains respectively. In ten male brains of adults free from brain disease, and ranging from twenty-five to thirty-six years of age, the internal carotid arteries had an average diameter of 2·8 millimetres on the right side and 2·75 millimetres on the left side, while the vertebral arteries had an average diameter of 2·2 millimetres on the right side and 1·875 millimetre on the left side; whereas in ten female brains of adults free from brain disease, and ranging from twenty-five to forty-three years of age, the internal carotid arteries had an average diameter of 2·6 millimetres on both sides, while the vertebral arteries had an average diameter of 2·3 millimetres on the right side and of 2·075 millimetres on the left side. It thus appears that the distribution of the blood in the male and female brain respectively varies to a considerable extent. The internal carotid arteries, with their great branches—the anterior and middle cerebral arteries supplying the supra-orbital convolutions and island of Reil, the gyrus fornicatus, the Rolandic area, the angular gyrus, and the first temporo-sphenoidal lobule—are much larger both absolutely and relatively in the male than in the female brain; but the vertebral arteries which supply the occipital and temporo-sphenoidal lobules are larger in the female than in the male brain, and the basilar artery, which is practically a continuation of the vertebrals, is also larger in the female brain, where its average diameter is 2·8 millimetres, than in the male brain, where its average diameter is 2·675 millimetres. It might be thought that the free anastomosis provided by the circle of Willis renders comparatively unimportant differences of calibre in the internal carotid and vertebral arteries, and must equalise the blood currents to the different regions of the cerebrum; but the fact is that the posterior communicating arteries, which, when dilated after the occurrence of any pathological obstruction on the cardiac side of the circle of Willis, maintain the circulation in the brain in tolerable integrity, are incapable while normal, by their calibre and position, of adjusting the balance between the direct currents of the carotid and vertebral arteries, and it is certain that the result of the difference in the diameter of these in the two sexes which I have recorded is this: that the anterior region of the brain is comparatively more copiously irrigated with blood in men and the posterior region in women. And vascular supply is in some degree a measure of functional activity, the flow of blood to an organ or part having always a relation to its working power. But the region of the brain which in men is most richly flushed with blood is that which is concerned, we have reason to believe, in volition, cognitions, and ideo-motor processes; while the region which in women is most vascular is that which is mainly concerned in sensory functions, and we thus see that there is a relation between the size of the cerebral arteries, and what observation has taught us as to the intellectual and emotional differences of the sexes.

Digitized by Google

The structural differences between the male and female brain, which I have briefly referred to, justify the conclusion that they are organs broadly distinguished from each other, and that they have to some extent different kinds of work to do, and an inquiry into the functional relations of each with other viscera of the body, did time permit of it, would strongly confirm this view. All through life the male brain differs from the female in capacities, aptitudes, and powers. Differences early assert themselves. Thackeray has said that little girls make love in the nursery and practice the arts of coquetry on the page boy who brings the coals upstairs; and as for the page boy, it is certain that his pugnacious propensities are already fully developed and have brought him into conflict with his brother buttons. And differences are most patent of all in the prime of life when man "for contemplation and for valour formed" by "his fair large front and eye sublime" declares "absolute rule," and when woman, "grace in her steps, heaven in her eye, in every gesture dignity and love," stands conspicuous for "softness and sweet attractive grace." And differences subsist to the last. The aged spinster, left in "maiden meditation fancy free," lavishes her altruistic emotions on cat, poodle, or parrot; and the hoary veteran, fidgety and irascible, concentrates his egotistic attention on his own liver. And these differences in brain structure and function, which at every stage of existence separate the sexes, have, as I shall presently show, a special pathological significance at the period when sexual divergence is taking place most rapidly, and when education is being pushed forward with most vigour. Education from first to last can only be safely conducted in the light of cerebral physiology, but unfortunately those charged with the conduct of education too often dispense with that light, or regard it as misleading. It is to point out to you the risks that are run by dispensing with that light at a particularly dark and tortuous part of the educational highway that I am here this evening. I am going to notify for warning and guidance some of the perils to health which seem to me to attend the high-school education of girls, which is now so popular.

I have no wholesale indictment to bring against high schools for girls. They have done good service to sound education, have widely diffused its benefits, have supplanted second-rate boarding and venture schools which were hotbeds of namby-pambyism, and have opened up to girls interests and helpful attainments which were formerly denied them, thus saving some of them from a vapid and weary existence. But, at the same time, it seems to me that these schools have serious drawbacks attending on them, and that their work is apt to involve very grave dangers to health—dangers immediate and prospective—which have not yet been sufficiently appreciated.

Even from an educational point of view, the work done by high schools for girls is not all pure gain. Their eulogists would have us believe that they have led forth great hosts of girls from a wilderness of ignorance and ineptitude into a land flowing with wit and learning. But that is sheer nonsense. What they have done is to conduct them from the unkempt meadows of natural growth into the trim gardens of artificial culture. Excellent are orchids and camellias in their way, but do not let us forget the buttercups and daisies. Before the high-school era dawned girls lived and learned and reasoned in a way, and in introducing them to the higher erudition these schools have withdrawn them to a large extent from homely household occupations which were not without their educational value, and have substituted the dogmatic teaching of the hireling for the precept and example of the mother. So much is this the case, and so impossible is it for growing girls exhausted by five or six hours of school-work and private study daily to make themselves acquainted with domestic economy, that it seems to me essential that high schools, if they are faithfully to prepare their pupils to become efficient wives and mothers, should add housewifery in all its branches to their present curriculum. Two years ago I met in the country a high-school girl who was reading Lucretius for her recreation, but she failed lamentably in the task I prescribed for her—that of boiling a potato. Now I am sure much more of the happiness and wholesomeness of life hinges on the boiling of potatoes than on the interpretation of Lucretius and his dark and doubtful sayings. And not only do high schools for girls deprive their pupils to a considerable extent of home-lore and practice in the simple but captivating arts of the kitchen and the still-room, but they tend to induce in them sameness and narrowness of intellect. These schools cannot vary or adapt their teaching to individual tastes and talents, but have one keynote for all, and so sacrifice to clearness of utterance many delicate inflections and cadences of faculty. They tend to make education mechanical. Then they so absorb the energies of their pupils, and so persuade them of the paramount importance of their school work, that these pupils have neither inclination nor strength to travel beyond their compulsory studies. With brains like wrung sponges, and well assured that there is nothing worth knowing beyond the attainments of the sixth form, high-school girls rarely leave the groove in which they find themselves. It will not be denied that home-reared girls read much more widely than do high-school girls. "They browse unconfined," to quote Mrs. Gaskell, "on the wholesome pasturage of English literature," while high-school girls are stall fed on condensed primers; and the result is that there is often a breezy freshness and interesting diversity about these home-reared girls that contrasts not unfavourably with the dry precision and monotonous uniformity of their more systematically educated sisters.

But it is not about the educational advantages or drawbacks of high schools for girls that I wish to speak, but about the dangers to health which lurk in their aims and methods—dangers very real, very serious, very imminent—all arising out of forgetfulness of sexual differentiation, and out of the futile attempt to educate boys and girls on exactly the same lines.

Now, I do not hesitate to affirm that over-pressure is rampant in high schools for girls in this country to-day. Of course there are high schools and high schools. Much depends on the head mistress. If she is judicious and sympathetic, over-pressure is reduced to a minimum. If she is hard and keen, it is raised to a maximum. But, whatever the disposition of the head mistress may be, over-pressure exists and is promoted by directors jealous of the honour of their schools and not averse to dividends; by parents anxious about their daughters' prospects in life, earnest to obtain the best possible return for fees paid, or not unwilling to hide their own dulness under the lustre of having clever children; and by the girls themselves, who, when the spirit of emulation is stirred in them or the fear of failure conjured up, strain eagerly forward and ignore all warnings and restraints. I willingly admit that in high schools for girls generally there is a sincere desire to avoid over-pressure, and that precautionary measures to prevent it are adopted; and I have no doubt that during the last five or six years there has been considerable mitigation of it, as a consequence of a limit put to the scramble after examinations and certificates. But I am confident that, notwithstanding all precautions and mitigations, over-pressure still prevails in these schools extensively, and sometimes acutely, and that it will prevail as long as they imitate schools for boys, fail to recognise sexual distinctions, and to modify their methods in accordance with these. They are, as I have said, pushed on to over-pressure by certain extraneous forces; but the tendency to it is inherent in their constitution, and will assert itself from time to time with greater or less violence, apart from outside influences, until that constitution is altered. I have no doubt that this statement of mine that over-pressure exists in high schools for girls will be strenuously, perhaps scornfully, denied. These schools have many attractive features, and are doing good work; the girls seen streaming in and out of them look healthy and happy enough, and those who are content to judge by superficial appearances will pronounce them sound to the core. Stethoscopy and endoscopy medically applied are necessary to get at their weak points. Then, again, there are those who believe that over-pressure is merely a medical myth; that there never was or could be such a thing in the beneficent realm of education, and they will of course dispute my thesis. I read some time ago a paper by a distinguished authority on educational subjects, Dr. Emily Bryant, in which she argued that it is impossible to overwork girls, their inherent indolence and frivolity being proof against any stimulus that can be applied to them. Well, I would answer Dr. Emily Bryant that it is possible to overwork horses—witness splints, curb, thorough-pin, and back sinew; and surely girls are not more obdurate than horses. And I would tell her further that a cloud of competent witnesses can be summoned against her, for while many high-school mistresses will doubtless deny

Digitized by Google

that girls are overworked in the establishment under their care, they will one and all admit that overwork is a contingency against which they have to be constantly on their guard. Some high-school mistresses of the more enlightened type frankly admit and deplore the existence of over-pressure even now. One of them said to me not long ago: "Certainly some girls in the upper forms are delicate, owing to too close application to their studies, and it is terrible to contemplate the ruin that might be wrought amongst them were they to be ruthlessly urged on and subjected to competitive excitement."

For obvious reasons it is difficult to get direct and trustworthy evidence about over-pressure in high schools. These schools are naturally disinclined to permit the exposure of blots on their own escutcheons, and individual cases of over pressure have to be delicately handled. But, thanks to the kindness and magnanimity of the head mistress of one English high school—one, too, in which special precautions against over-pressure were taken,—I obtained a few years ago a return which I regard as of great interest, and which throws some light on the matter. (See Table II.) The facts on which this return is founded were got at by questions, put and answered in writing, the answers sent in by each girl being afterwards tested by private cross-examination by her form-mistress, and in some cases by communications with parents, so that the return is, I believe, absolutely reliable; and it is certainly not a little remarkable to find from it that of 187 girls belonging to the upper and middle classes, well fed and clad and cared for, and ranging from ten to seventeen years of age, as many as 137 complained of headaches, which in sixty-five instances occurred occasionally, in forty-eight frequently, and in twenty-four habitually. Sir Richard Owen once said to me: "Children have no business with headaches at all, and if you find that these occur frequently in any school, you may depend on it there is something wrong there." And so, I take it, there must be something radically wrong in high schools that produce so copious a crop of cephalalgia. That the headaches dealt with in this return were connected with school work is, I think, made probable by the fact that, while in twenty-six cases they are stated to have occurred in the morning, in as many as seventy-six they are set down as of most frequent occurrence in the afternoon and evening, when, as you will notice, according to an immense majority of the girls, the hardest part of the day's work falls on an already jaded brain. And there are other significant facts in this return, besides those relating to headaches, for you will observe that as many as thirty-seven of the 187 girls were shortsighted, and that four of them exhibited choreic movements. And this return represents no exceptional state of things. Inquiries made quite lately satisfy me that a very large proportion of high-school girls still suffer from headache, that neuralgia is common amongst them, and that they display multifarious indications of nervous exhaustion. It is no infrequent occurrence, I am told, for the more delicate girls, who return after the holidays looking tolerably well, to break down in the middle of the term, to be absent from school for a few days or weeks, to return and struggle on with their work, but finally to shirk the examination at the close of the term. But if we had no evidence of suffering or disability immediately resulting from high-school training as it is now carried on, we, as medical men, should not hesitate to pronounce that training in some respects pernicious, from a consideration of its character alone. Two-thirds of high-school girls will attest that the hardest part of their work—preparation, which involves the opening up of new ground, an advance on what has been already learnt, and effort in surmounting obstacles—has to be performed in the evening, when they are already worn out, at the very time when in the cycle of daily life, their brains are least capable of exertion. And no inconsiderable number of high-school girls will attest that this arduous work of preparation is often carried on until ten, sometimes even until eleven o'clock at night. Within the last month I came upon two girls attending a London high school, bright, clever, ambitious girls of fifteen, high in their classes and determined to hold their places, who admitted that, in spite of all restrictions, they were working up till ten o'clock two or three nights a week, and in one of them I could discern, in stunted growth, round shoulders, and intense nervous susceptibility, the effects of this ill-timed diligence in study. A friend of mine in the north of England tells me that he has recently removed his two daughters from a high school and placed them under private tuition, because he found that they were regularly working up till ten o'clock at night.

The high-school authorities will of course pronounce such proceedings irregular, and endeavour to shift the responsibility for them on to the shoulders of parents. Their rules as to home work look reasonable enough on paper. This work, they will tell us, should be done during the afternoon, either in school or at home; but girls who have been in school from nine till one, using their brains, are not dis-

posed to resume work immediately after their mid-day meal. They need change, fresh air, and exercise, which in this climate must, for a great part of the year, be taken in the afternoon, if at all; and many of them continue brain work in the afternoon under the veiled form of accomplishments, such as music and drawing. For these reasons, as well as from the claims of family and social intercourse, it comes about that a large proportion of high-school girls postpone their preparation until the evening, when they do it slowly, laboriously, with least benefit and most risk. The work which was calculated to occupy two or three hours is spread over three or four, and perturbs the brain just when it should be subsiding to rest. The time-tables or cards issued to pupils and parents, defining with the utmost nicety the number of minutes that are to be devoted to preparation in each particular subject on each particular day, fixing a maximum duration of home work (generally from two to three hours), which is not to be exceeded without an intimation of the fact to the head mistress, are practically useless, and sometimes worse than useless, for they lead to deception. Not one girl in ten steers by these charts; not one parent in ten reports the transgression of their terms. Girls work at very different rates, and at very different rates in different subjects, and the number of minutes allowed for Euclid, Latin, German, History, or Science respectively, which may be amply sufficient for a girl of nimble wits, may be altogether inadequate for one of slow comprehension, and hopelessly ill-adjusted for one of special gifts. The relation between the time allowed for home work and the amount of home work allotted is often very difficult to discover, and the highly conscientious girl who tries rigidly to adhere to the instructions given will generally find herself at a disadvantage at school. Parents for the most part ignore the school time-tables. They do not always know the exact length of time given by their daughters to home work; it is sometimes secretly prolonged when they supposed it to be finished; and they find that any expostulations as to its amount which they may address to the head mistress are highly distasteful to their daughters, who fear that they will be regarded as stupid or as a drag on the class for failing to accomplish their tasks in the prescribed time, or that blame for over-burdening them will be laid on their form-mistress, and of course blame does not conduce to amiability of feeling towards those who have procured its infliction.

The truth seems to be that the checks imposed upon home work are nominal and not real, and that what high-school authorities have to do is largely to reduce it in amount, and in the case of young girls to abolish it altogether. The drudgery of education should be done in school with skilled assistance, when the brain is in its prime vigour, not at home unaided, or with only precarious parental help, when the brain is already fatigued. I feel strongly that no girl from ten to seventeen years of age should have any forced brain work to do after 7 P.M., and that a reduction is required in the number of hours that high-school girls are now called on to give to brain work. Our brawny colliers clamour to have their bodily labour restricted to eight hours a day. Shall we permit our fragile girls to engage in mental toil for an even longer shift?

I have given prominence to the question of home work in connexion with high-school education, because I regard it as one of the chief evils of the system; but in connexion with the school work there are several topics that are eminently worthy of medical consideration. A criticism of the curriculum and of the subjects taught cannot be undertaken here; but a word must be said about the competition which is still encouraged in some quarters. Nineteenth-century girls at the age of puberty cannot stand competition. It is intellectually and morally injurious to them, and disturbs the equilibrium of health. "Nothing," says Ruskin, "is ever done beautifully which is done in rivalship, nor nobly which is done in pride," and nothing, I would add, is ever done safely by girls which is done in emulation. That should be banished from their education, and marks, places, and prizes tabooed. And examinations, too, which harass and agitate, should be as much as possible avoided. For girls who have to earn their own living examinations may be necessary trials of fitness; but for the bulk of high-school girls they are gratuitous miseries, or mere opportunities of vainglorious display.

I have admitted that in some high schools the authorities are on the alert on the subject of over-pressure, and according to their lights do their best to ward it off. But it is a melancholy fact that some of the expedients resorted to with this purpose tend to aggravate rather than to abate it. One head mistress told me proudly that her practice was, whenever the girls in any form began to get very sluggish and drowsy at their work, to close the books and give them ten minutes' hard drill. She thought I was joking when I said that she had much better put them to bed and give them candle; but I was quite serious, for muscular fatigue is not the remedy for cerebral exhaustion, although it is very commonly believed to be so. Indubitably there is temporary easement in shifting a burden from place to place. A man who has been standing on one leg for some time finds it a relief to change to the other; but the expenditure of nervous energy is going on all the time, and the brain that is wellnigh drained dry needs rest and will not be replenished by merely altering the channel of outflow. Drill is highly to be commended in its proper place—so are gymnastics, so are games; but they will not create a tolerance of mental over-pressure or counterbalance its evils. It is quietism, not athleticism, that has to be preached in high schools in the first place. I have even my doubts about compulsory hockey and cricket in the country on half-holidays. I cannot help thinking that a girl should have just a little scrap of her own life left to her to do with exactly what she likes, and with all respect for physical education—the boom of which is upon us—I have more faith in the life-saving qualities of a good, merry, spontaneous, exuberant romp, than in all its ingenious, elegant, and hygienically designed exercises.

The evils resulting from over-pressure in high schools for girls—whether that over-pressure be due to home work, or competition, or examination strain—are brought about through its influence on the cells of the brain, and it is not difficult to understand how these cells are affected. It is unquestionably true of all cells that when they are in any way stimulated in excess of their powers of taking up nutriment, or deprived of an adequate supply of nutriment, they utilise as food material their own protoplasm, and so induce disordered metabolic processes with subsequent degeneration. In pyrexia, in the presence of which metabolic activity is always increased, we find that the protoplasm of the muscular fibres of the heart and of the cells of the liver passes through a stage of cloudy swelling, indicative of increased activity, which merges ultimately into fatty degeneration. And when to the stimulating influence of pyrexia is added that of toxic materials circulating in the blood, as during typhoid fever and diphtheria, we find that degenerative changes are not confined to the excretory glands and heart, but invade the nerves and muscles generally. Well, it appears to me that the fever of the mind which over-pressure sets up is capable of influencing cell protoplasm in much the same way as ordinary pyrexia. Its effects have not yet been traced out with the same precision. No doubt they differ in degree and distribution, but they are probably much the same in kind. When the cells of the brain are stimulated in excess of their powers of taking up nutriment, as they are during forced mental labour, or when suitable supplies of nutriment are cut off from them, as may be the case during the impairment of digestion which forced mental labour not rarely entails, then the metabolism in these cells is, we may infer, altered, and they degenerate and secondarily induce widespread degenerative changes throughout the system. The group of symptoms which is characteristic of the mental failure which follows upon severe over-pressure, and which may be summed up as acute or apathetic dementia, is almost identical with that seen in cases in which mental failure has followed upon acute specific diseases, and in mental failure of the former kind, not less than in the latter, we have also sometimes dilatation of the heart and changes in the liver, kidneys, and voluntary muscles; and in both kinds of mental failure recovery takes place if the fatty degeneration has not so far advanced that the active protoplasm of the cells is absorbed, whenever the cells which have had extra work thrown upon them are allowed absolute rest, and are placed in favourable conditions as regards nutrition.

I have referred to acute or apathetic dementia as the most characteristic of the pronounced mental changes which severe and continued over-pressure acting on a neurotic subject may induce, and the slight mental changes which are similarly induced are most generally akin to it, and are but the buds of the symptoms which it presents full blown.

Digitized by Google

Thus it is no uncommon event to hear overworked high-school girls complain that their power of acquisition and attention is impaired, that they take far longer to their work than they used to do, that they cannot remember what they have learnt, that they read their lessons without understanding them, that they sometimes lose themselves and forget where they are, and that what they call "queer thoughts" keep coming into their minds, while the observation of these girls at the same time reveals that they are languid and irresolute, or unusually irritable. Such slight departures from normal mental states for the most part go no further, but are rectified by the holidays; but now and again they advance into that mild coma which corresponds with apathetic dementia. But, besides apathetic dementia, there are, of course, many other mental aberrations to which over-pressure may lead up, the nature of these in each case being determined by the inherited tendencies, antecedents, or environment of the girl. We may have cyclones of mania, or anticyclones of melancholia, hurricanes of morbid impulses, or the settled bad weather of moral perversion. And as regards certain minor mental changes which thus arise, it is noteworthy that they are often concealed by girls who do not comprehend and can scarcely describe them. This is particularly the case with reference to those voluminous mental states described by Dr. Hughlings Jackson which are sometimes the harbingers of epilepsy.

I cannot pretend to classify or describe the vagaries of nervous disturbance that present themselves to medical observation in girls in these days, and in the production of which over-pressure plays some part, but I would name insomnia of the commonest occurrence, often of evil import, sopor or sleep so deep and difficult to break as to be almost cataleptic in nature, neuralgia, chorea, and hysteria. And, besides nervous disturbances, there are many ailments and diseases begotten or fostered by over-pressure which medical men are familiar with in high-school girls in these days. Chief of these are anæmia and general delicacy. Women suffer from anæmia in far larger proportion than men. In the ten years 1881 to 1890 the deaths from anæmia, chlorosis, and leucocythæmia in England and Wales were 33·29 per 1,000,000 amongst men, and 54·83 amongst women. And, as is well known, chlorosis and anæmia show themselves in girls from ten to twenty years of age more frequently than at any other period of life, and may be induced by mental worry or excitement, which causes a diminished production of blood-corpuscles. In his very able investigation into the physical and mental condition of school children, Dr. Francis Warner has satisfied himself that mental stimulus applied to children "does lower their general nutrition." He found that pale and delicate-looking children are proportionately more numerous in schools attended by children of an upper social class and presumably well fed, than in schools attended by children of the poorer class, presumably not well fed; and the only explanation of this he has to offer is that better-class children are subjected to more mental stress than children of a poorer class. A single glance at some high schools, and the complexions of the girls assembled in them, convinces that they are deficient in red corpuscles, however rich they may be in blue stockings.

The anæmia encountered in high-school girls is sometimes due to the direct action of mental tension on the blood-forming apparatus; but it is sometimes due also to the action of that tension on the digestive functions. Large numbers of high-school girls suffer from loss of appetite; a certain number go to school without breakfast. Worn out, they oversleep themselves, and leave scant time for the morning meal; or, after a night of broken rest, they rise unrefreshed, swallow a cup of tea, the neurotic properties of which they have already discovered, but decline solid food, or merely trifle with it. They labour under a gastric disorder now so common that it might receive a distinctive appellation, and be called *anorexia scholastica*, in which the lessened flow of energy from the exhausted nerve centres retards the functions of all the abdominal viscera. Buns in the forenoon, a regular institution at all high schools now, are very well in their way, but they do not compensate for a lost breakfast, and I hold that no girl who has shirked that meal should be allowed to go to school or engage in brain work. It is an axiom that nutrition comes before education.

I have spoken of some of the immediate evil effects of over-pressure in high schools—effects which medical men have long recognised, which parents are beginning to perceive—and I wish now to direct your attention to what will probably be its remote effects if it be allowed to go on—effects for which we must wait, but which we have grounds to anticipate with some confidence. The ailments of girlhood which we have ascribed to over-pressure do not always end with the cause that induced them, but are apt to plant themselves permanently in the system they have infested, or to blossom into something worse. The headachy girl is not unlikely to grow into the migrainous and invalid woman. A voluminous mental state may develop into epilepsy, somnambulism may lead to hysteria, insomnia lay the foundation of insanity, and anæmia at the growth period may entail lifelong debility. Over-pressure operates upon the high-school girl at a great epoch of her life—at puberty and during the pre- and post-pubertal periods—when momentous changes are taking place in her body and mind, and when a wave of irritability sweeps through her nervous system. The increase of stature and weight of the girl, according to Dr. Bowditch's recent observations, goes on much more rapidly than that of the boy from the tenth to the fourteenth year, and, while her pelvis is expanding, her special organs and mammæ and sebaceous glands are developing and becoming more vascular, and her physical energies are gathering strength under the governance of new impulses, there exists in the girl a special proclivity to disease, and to the assumption of morbid tendencies. This epoch from the tenth to the seventeenth year is unquestionably the plastic period—it is the golden opportunity for education; but the education that goes on then is not limited to the higher cerebral centres, as teachers fondly imagine, but pervades the tissues. Functional habits are being everywhere formed, and vicious habits are not unlikely to be contracted by certain organs if habits of thought are too assiduously practised. The grand truth to be inculcated in all high-school authorities is this—that they have to deal with girls at a period of life when vital resistance is greatly reduced, when the liability to disease is proportionately augmented, and when physiological indiscretions are peculiarly hazardous.

The proof of this can be readily supplied. Let us examine the incidence of zymotic affections upon the sexes. Throughout life, in every quinquennium, the mortality of males from small-pox exceeds that of females, and that in a very marked degree, except in one quinquennium from the tenth to the fourteenth year, when the female exceeds the male mortality, being again but very slightly behind it in the succeeding quinquennium from the fifteenth to the nineteenth year. At all ages the male death-rate from enteric fever exceeds that of females, but the female mortality is very considerably higher from the third to the twentieth year of life. In infancy and also in old age the male mortality from diarrhœa and dysentery exceeds the female mortality, but in the child-bearing period, from fifteen to forty-five years of age, the mortality is distinctly higher amongst females. And even more striking in this connexion are the statistics of phthisis than those of zymotic diseases. As you will notice in this table, phthisis

TABLE III.—*Phthisis: Mean Annual Death-rate per Million living at successive Age Periods and per "Standard Million" at all Ages during the Ten Years 1881–1890.*

is more fatal to males than females under five years of age; but then a change takes place, and from five to ten it is much more fatal to females than to males, while from ten to fifteen it is more than twice as fatal to females as to males. From fifteen to twenty phthisis is still much more fatal to females than to males; from twenty to twenty-five the mortality from it is exactly equal in the two sexes, and

Digitized by Google

from twenty-five to thirty, and at all subsequent ages, the mortality from it is much greater amongst males than amongst females.

Now this distribution of phthisis mortality, especially when viewed in connexion with the fact that the reduction in it, which is happily going on at all ages, has been proportionately less of late years amongst females than amongst males from five to fourteen, is highly significant. It is not of course suggested that high-school operations have had anything to do with this diminished reduction. The total number of girls attending these schools is so small in comparison with the population that no amount of mischief they could do would appreciably affect the Registrar-General's returns. But the fact that there is a special proclivity to phthisis in girls from five to twenty years of age, and that girls between these ages are not sharing as fully as boys in the benefits of the preventive measures which we owe to modern sanitation, viewed in connexion with the conditions of high-school work, suggests very pointedly that one of the remote evils of over-pressure in them will be the propagation of phthisis in those who have been subjected to that over-pressure. The nervous erethism which is characteristic of the growth period in girlhood obviously much increases the liability of the sex to phthisical disease, and as over-pressure aggravates that nervous erethism, it must still further increase that liability. The connexion between states of the nervous system and pulmonary tuberculosis has not yet been clearly defined, but this much may be taken as established, that nervous depression and exhaustion alike open wide the door for the invasion of the tubercle bacillus. And so it is that the nervous exhaustion due to over-pressure in high schools for girls may be expected to induce a peculiar vulnerability of the pulmonary tissue, which must be intensified by the conditions of work in these schools. The in-door life of the girls, their sedentary habits, and the stooping posture in which they pass much of their time, bring the lungs into a state that is favourable to tuberculous infection. The lungs are comparatively immobile, and there is consequent inactivity of the respiratory current in them, with a tendency to congestion and catarrh.

If it were our object to secure an abundant harvest of phthisis, I do not know how we could better set about it than by providing for general over-pressure in schools for girls. Keep a large number of town-bred girls in a constant state of nervous tension, so as to abbreviate sleep and impair appetite, deprive them as much as possible of fresh air, insist on their writing and poring over books for prolonged periods, and scatter amongst them a few cases of tubercular disease, and you will inevitably in the fulness of time have a rich growth of phthisis. My own experience is necessarily of the most limited description, but I have seen a case of phthisis in a high-school girl and two cases in high-school mistresses which I was disposed to attribute to high-school life; and of this I am sure, that phthisis must be one of the most certain and disastrous of the more remote effects of the over-pressure of girls during their growth period.

But the special proclivity to disease of girls at the growth period, and the influence of the nervous erethism by which they are then visited, may be traced out not only in zymotic diseases and in phthisis, but in nervous diseases themselves. Suicides which spring from causes identical with those that are productive of insanity, and which are an expression of mental disorder, are four times more numerous amongst men than women, and the male death-rate from suicide is much greater than the female at all ages, except, strange to say, from fifteen to twenty, when the female death-rate rises considerably above the male. The rate of increase of suicides during the last twenty years has been much higher amongst women than amongst men. Chorea, which is at all ages more fatal to females than to males, reaches a rate of mortality amongst females from ten to twenty years of age that is phenomenal when contrasted with the rates at other ages and in connexion with the mortality from this disease; it is of extreme interest to note that, while the male mortality due to it has declined during the last thirty years, the female mortality has risen, and has risen rapidly, during the last ten years. Chorea is seldom fatal, and the increase of the death-rate from it amongst girls must betoken a large increase of the malady in its milder forms. And chorea, be it remembered, is a malady which, perhaps more than any other, may be directly attributed to over-pressure and nervous strain.

I might go on enumerating nervous and other diseases the mortality from which mounts up from ten to twenty years of age in girls, but enough has been said to show that there is a dangerous instability of the nervous system at this epoch. And indeed the most convincing proof of this instability is to be found, not in the mortality returns, but in the extraordinary prevalence, during this section of female life, of functional nervous disorders, which do not kill, but cripple and perplex, and are often the source of misery long drawn out. Man is at all ages more prone than woman to organic diseases of the nervous system, but woman is more prone than man to certain functional disorders, and especially to such functional disorders as display themselves about the period of puberty. Then it is that women succumb to epilepsy, neuralgia, hysteria in all its protean shapes, chorea, migraine, neurasthenia, the milder forms of insanity; then it is that the nervous system is unstable and explosive in a peculiar degree, and especially liable to be influenced, for weal or woe, by the treatment to which it is subjected. Judicious treatment at this time gives it balance, and perhaps steadies it for life. Injudicious treatment—and what treatment can be more injudicious than over-pressure?—either makes it topple over at once or sets it swaying in a way that must mean final overthrow on the occurrence of any further interference, however slight. Let high-school authorities ponder all this.

It has just been mentioned that men are much more liable than women to gross structural lesions of the nervous system, including the various forms of inflammation of the brain and spinal cord, and their membranes, paralysis, locomotor ataxia, muscular atrophy, and abscess and tumours of the cerebrum; and there can be little doubt that their greater liability to these lesions is dependent upon—firstly, the innate higher metabolic activity of their nerve centres; and, secondly, their greater exposure, during the struggle for life, to the causes of nervous disease. Women owe their comparative immunity from organic nervous disease to their anabolic habit, and to the comparatively tranquil and sheltered lives which they have led. But if all this is to be altered, if women are to be made as katabolic as possible, and are to take part in the struggle for life on equal terms with men, then it follows that they will have to a great extent to sacrifice the comparative immunity from organic nervous diseases which they have hitherto enjoyed. During the ten years 1881 to 1890 409 men per million living died in England and Wales from the effects of fractures of bones, but only 100 women per million living so died. The explanation of this is clear. The number of men engaged in occupations which expose to accidents is to that of women engaged in such occupations as 4 to 1. But if in our wisdom we ordained that men and women should share equally in manual labour of all sorts, it is indisputable that we should have the mortality from fractures amongst women mounting to as high a point as it has now reached amongst men; nay, the probability is that it would greatly transcend that point, for the employment of women in all sorts of labour would probably increase the number of accidents, while their anatomical configuration would involve their suffering more severely from their effects. During the ten years 1881 to 1890 2·69 men per million living died of tetanus in England and Wales, but only 0·84 women per million living; clearly because for every one woman who in her employment has to handle earth three men have to do so. Expose men and women in an equal degree to inoculation by the tetanus bacillus and they will in equal degree perish from its attacks. Now will it be doubted that the same thing holds good with regard to other causes of disease which operate upon the nervous system, and that the comparative exemption of women from organic nervous disease is to be attributed largely to the fact that they have not been exposed to these causes to anything like the same extent as men? Five men suffer from the motor form of writer's cramp for every one woman who so suffers, and the explanation of this lies on the surface, in the fact that men are employed in writing far more numerously than women. Four men die of general paralysis of the insane for every one woman who so dies. Is it not feasible to suppose, then, that women owe their comparatively small liability to this fell malady to their comparative freedom from the stress and striving of professional and business life, which so often lead up to it in men? To make women katabolic—and that is, I maintain, what high-school education tends to do, to throw them into competition with men, and that is, I maintain, what some high-school education aims at—is to ensure to them a largely increased liability

Digitized by Google

to organic nervous disease. And so over-pressure from ten to seventeen years of age may have amongst its remote consequences, not only the reproduction in the same or modified forms of the functional nervous disorders which so often manifest themselves at that period, but a crop of gross nervous degenerations, which have, up to this time, been rarely seen in women. And notwithstanding all Weismann's arguments, I would say, "Woe betide the generation that springs from mothers amongst whom gross nervous degenerations abound!"

The study of the effects of over-pressure, immediate and remote, on the monthly rhythm, and on the fitness and capacity of the woman to reproduce the species and to bear healthy children—health implying both bodily and mental vigour—must be kept for separate examination at some other time. So also must a study of the effects of secondary over-pressure, as applied, in colleges and halls, to young women at from eighteen to twenty-four years of age. Admirable culture is supplied in these colleges and halls; but they, too, have their risks, notwithstanding that their pupils are all picked lives. The suicide of a pupil, who had just undergone examination at one of them, was reported two months ago. I must, however, even now express my belief that the University of St. Andrews, in deciding, as it has lately done, to open all its classes in Arts, Science, and Theology to women as well as men, has taken not a retrograde step—for our ancestors never did anything so foolish,—but a downhill step towards confusion and disaster. Its now empty benches may be thronged with pupils, its professors may batten for a time on duplex fees; but the attempt to educate young men and women, not only on the same lines but in the same coaches, cannot but prove injurious to both. "What was decided amongst the prehistoric protozoa cannot," it has been well said, "be annulled by Act of Parliament," and the essential difference between male and female cannot be obliterated at a stroke of the pen by any Senatus Academicus. To essay such work is to fly in the face of evolution. Amongst unicellular organisms the conjugating cells are exactly alike, and do exactly the same work in the world; but amongst multicellular organisms they are dimorphic, and from that point upwards differentiation in structure and function goes on. With occasional aberrant variation the sexes diverge from each other, not merely in primary and secondary sexual characteristics, but in functions, not directly associated with sex, as we ascend in the animal kingdom, and it is in the human species that sexual distinctions, bodily and mental, are most marked.

And with this divergent differentiation of the sexes has come more reciprocal dependence and higher harmony. It is no question of superiority or inferiority of the one sex to the other. Each sex is higher; each is lower; together they make up the perfect whole. Separate they are infirm; in union they are strong; in competition they are mutually destructive. It is in the sympathetic accord of the differentiated sexes that human progress can alone be hoped for.

> "He is a half-part of a blessed man,
> Left to be finished by such a she,
> And she a fair divided excellence,
> Whose fulness of perfection lies in him."

And blindness to this complementary relation of the sexes, so patent to Shakespeare, it is that leads wise men—wise but ignorant, or contemptuous of biology—to sanction intersexual competition in education, and for subsistence with its ruinous effects. Men and women are constitutionally adapted to do different work in the world. To set them to do the same work is wasteful, and detrimental to the sex that is less adapted to it. It is impossible to contemplate with complacency some of the experiments in this direction which are being carried out, and it is impossible to speculate, from a medical point of view, without apprehension what the outcome of such experiments may be, or what high-school, and college, and hall education may do for the country in a few generations, if they be pushed on with relentless zeal.

Those tall, graceful, lovely English girls whom we see around us so plentifully to-day, and never in the world's history has woman's beauty been so beautiful as it is in England to-day—those tall, graceful, lovely girls are the offspring of mothers who had not the advantage of a high-school education. What will the next generation of English girls be like? I saw a vision once that has haunted me ever since. It was of a score of sweet girl graduates from a celebrated college, standing together in a group on the platform of a provincial railway station, waiting for trains to carry them home at the end of the term. Sweet they were I doubt not; most of them carried musical instruments, but they were not, upon the whole—well, not just—"fairest of the fair" to look upon. I am afraid I shall be called ribald and profane, but I should describe them as pantaloon-like girls, for many of them had a stooping gait and withered appearance, shrunk shanks and spectacles on nose. Let us conserve the beauty of our English girls very jealously. I would rather they remained ignorant of logarithms than that they lost a jot of it.

ABSTRACT OF

The Morton Lecture

ON

THE ETIOLOGY OF CANCER.

By G. SIMS WOODHEAD, M.D.,

DIRECTOR OF THE RESEARCH LABORATORY OF THE CONJOINT BOARD OF THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.

MR. PRESIDENT AND GENTLEMEN,—I understand that the Morton lectureship was established by its founder with the view, in the first instance, that the lecturer for the time should gather together and give in the form of a summary any fresh light that may from time to time be shed on the subject of cancer. Beyond this, however, the primary object of the founder was to stimulate thought and research in connexion with a disease the importance of an accurate knowledge of which is at present only equalled by the futility of all the efforts that have been made to elucidate even a few of the problems that a most cursory glance at the subject must at once suggest. We owe to histology and to statistics almost all the knowledge we have hitherto acquired, and most of the answers to such questions as have been solved. The clinician, to whom cancer has been one of the most absorbing studies, has done all that was within his power; but beyond determining the bounds of the periods of life during which it may occur, and the nature of the hereditary predisposition of certain subjects and tissues, this all has been but little. Even the attempts to associate the growth of cancer (and by cancer I shall to-day mean cancer in the strictest limitation of the term) with any specific causal agent have hitherto failed, and I must confess that until quite recently I have remained strongly of opinion that, although cancer may possibly be the result of certain forms of irritation, it can scarcely be looked upon as due to the vital activity of any specific micro-organism, whether animal or vegetable; in fact, I am not yet prepared to depart entirely from this position, though I must acknowledge that comparatively recent observations have been made which, if confirmed, would go far to limit the range of irritants which possibly may give rise to the proliferation of the special tissues with their special arrangement so characteristic of cancerous growths.

What I have to say to-day may be arranged under three heads:—1. The conditions within the tissues that may predispose to the formation of cancerous tumours. 2. What we know as to the nature of the irritants that are now assumed to play a specific etiological part in the production of cancers. 3. What is to be gathered in respect to the treatment of cancer from recent researches on the subject. It has frequently been insisted upon that the nucleus plays a most important part in determining the multiplication of cells. We may say, indeed, that the nucleus is the active part of the cell, in the sense that it is always the first part of the cell to undergo division. From the extraordinary size and distinctness of the nucleus and nucleolus of the cancer cell, some have gone so far as to indicate that these are practically sperm and germ cells respectively. Within these undoubtedly there is during the normal life of the individual a power of multiplication, a power which greatly varies at different stages of this life. As this power dies out under normal conditions a man dies of old age, and it is necessary for the continuance of the species that there should be a recurrence to a process of direct reproduction through the well-nourished ovum and the highly differentiated sperm cell, by the conjuction of which the cycle is recommenced.

Here we have, just as really as in the case of certain parasitic organisms, a kind of cycle or alternation of generation.

More than forty years ago, when Virchow brought forward his epoch-making doctrine that in all pathological as in all physiological processes cells beget their like, he at the same time shadowed forth the idea that, although all cells are begotten of other cells, the progeny only resemble their parents when they are produced under general conditions and surroundings, circumscribed within certain very definite limits. We now regard it as a well-known fact that by varying the conditions of nutrition, the facilities for excretion, and the nature and amount of stimulation or irritation, we can, to a certain extent, control or alter the character of the cells produced by certain tissues. Elsewhere I have indicated that it is necessary to study the epithelial tissues and the connective tissue separately, in order that we may be able to gain some insight into their relation to tumour growth. All epithelial surfaces are covered with a single layer or with several layers of cells, the forms of these cells varying very considerably according to the function that is assigned to them; in fact, they can only become fully developed as the necessity for some special function comes into play. Whatever epithelial cells we examine, and in whatever conditions, it may be accepted that the greater their vegetative power, the less completely is their functional activity developed. We have an exceedingly good example of this in what takes place in the embryo, where, development and growth going on rapidly, the cells are called upon to exert little or no function, and no draft is made on their energy and nutrition for carrying on of such function; the whole of these may therefore be devoted to reproduction. At the same time the connective-tissue cells are extremely active, although they in turn do not become fully developed, as we see from the mucous tissue that is found as the forerunner of the subcutaneous areolar tissue. It is during this period that all the in-foldings of the epithelium that take place in the fœtal tissues occur. Here we have the scaffolding of the whole gland erected long before it is called upon to perform any function; whilst in the developing mammary gland of the adult, when it first becomes active, the initial draft on its resources is in connexion with an active proliferation of the cells of the gland acini, and is not associated directly with any functional activity. During this period of development of the embryo within the uterus, and of the breast at puberty, we cannot describe either of the groups of tissues as being in a *stable condition*, and we can readily imagine that with any great nutritive disturbance, especially when this impairment is due to increased demand on the cells, due to local irritation, it may result in tumour growth.

Why do we get the age distribution of tumours that was insisted upon, now many years ago, by Virchow and Paget? Why are sarcomatous tumours so much more common during fœtal and early life than in old people? Why are the tumours of adult life those which have no great tendency to become malignant—adenomas, cystic glandular tumours, fibroid adenomas, or cystic sarcomas, in which we have always an increase in both sets of tissues, and which vary in one direction or another, becoming more sarcomatous or more glandular according to the age at which they are developed? Why are epitheliomas, as a rule, met with in old age, or rather at the end of adult life? May it not be that similar stimulating or irritating agents are capable of giving rise at different periods of life to these different forms of tumours, and that the essential difference consists in the different nutrient and developmental conditions of the tissues? I shall have something to say against this theory, but for the present let us look at it as affording some explanation of the occurrence of different tumours at different periods of life. In the embryo and during the first years of growth we have as yet an unbalanced condition of the tissues; the building-up process in which the connective tissues are specially concerned is going on at a great rate, and tumours occur in those tissues—the connective tissues,—on which the greatest strain is put under ordinary developmental conditions, and which therefore are, as it were, in a condition of unstable equilibrium; a comparatively slight increased stimulation being sufficient to maintain the vegetative activity at the expense of the true connective-tissue-forming power. In adult life, as has been frequently pointed out, the two sets of tissue may be looked upon as growing equally side by side; they are now both past the great vegetative strain, the connective-tissue framework has been completed, the functionally active gland cells have taken their position and part in the economy of the tissues, and both sets have settled down to their every-day work and to their every-day nutrition; the nutrition and function of the one appearing to be dependent in a very marked degree on those of the other. An increased growth of the one is accompanied by a similar growth of the other, and in both cases the cells are so far stable that their vegetative activity is never excessive. Local irritation or increased blood-supply may set up a localised hypertrophy, as it were; but beyond this we have no tendency to the formation of malignant tumours. During the period at which cancer is most usually developed, but when of course sarcomatous tumours may also occur, the connective tissues have passed their prime. The epithelial tissues have also reached their zenith, and are now on the turn; but, as we know, they have still great vitality, sufficient, indeed, when diverted from the imperfect functional to a vegetative activity, to give rise to very large masses of imperfectly developed epithelial cells which, as in the embryo, appear to have the power of invading the connective tissue. I have long been of the opinion that in classifying cancers and epitheliomas, the age of the patient is not the only factor that had to be taken into account; the organ affected must also be taken into consideration. We know that epithelioma of the skin and mucous membrane-tissue—which function is never highly specialised, but which remains longer than in the more specialised glandular cells—is usually developed later in life than cancers of the uterus and breast in which the function is lost at a comparatively early age. Epitheliomas, for instance, are probably commoner between the ages of sixty and seventy than at any other period.

Some time ago I examined a series of tongues taken from patients of different ages, and afterwards Dr. T. W. Dewar continued the investigation of the changes that take place in the epithelial tissues in a large number of tongues taken from patients at various periods of life. As the result of this examination I should like to bring under your notice several important facts which, up to the present, have not been systematically studied. If the tongue of an old person be examined the appearance is quite different from what is seen in the tongue of an infant; the subepithelial tissue is distinctly less in amount, whilst here and there are groups of small round cells; the fibrils of the connective tissue are wider apart and appear to be considerably atrophied. The epithelial covering, on the other hand, has assumed a very different appearance. The masses of cells, instead of being simple, are more or less ramified, small finger-like processes passing down from the main column into the connective-tissue spaces; until in some cases we might almost imagine that we were examining an epithelioma, especially where there are small cell-nests formed in the thickened epithelium. When this condition of affairs is normally present—for such a condition appears to be present in the tongues of most old people—it is easy to understand how some comparatively slight but long-continued irritation at this point may give rise to an epithelioma; we have practically an invasion of the much-atrophied and non-resistant connective tissue by the highly vegetative epithelium. Similarly in old people it has often been remarked that as involution of the breast proceeds the connective tissue becomes opener, the spaces larger, and the cells fewer; in fact, it becomes atrophied, and this atrophy becomes more marked as age advances. If during this period of atrophy there is no irritation, there comes a time at which the epithelium also undergoes atrophic changes, and there is a steady involution. Should there be any irritation, however, instability of the epithelial cells results; we have proliferative activity of these cells, an invasion of the non-resistant atrophied connective tissue, and the formation of a cancer.

It may be accepted for the present, then, that malignant tumours are to be looked upon as overgrowths of certain tissues started into activity by some unknown cause. This unknown cause has been a subject on which the pathologist has bestowed the most earnest attention. It has been recognised that it is necessary to search beyond the condition of the tissues themselves for a primary causal factor such as would account for the peculiar proliferation of different sets of cells under definite conditions and at certain periods of life. It has been found that malignant tumours of an epithelial type cannot be produced in healthy tissues, although certain adenomatous forms have been ascribed to the action of such irritants on compara-

Digitized by Google

tively healthy tissues. It has also been indicated that if the irritation that brings about this formation of simple tumours be continued for a considerable period, or if during the process of irritation a "cancerous age" is reached, a cancerous element—that is, rapid vegetative power of the epithelium leading to invasion of the lymphatics—is developed. What, then, can be the exciting cause of cancer formation? We have already spoken of the unbalanced condition of the tissues and of the vulnerability to invasion of connective tissues by epithelial cells under certain irritative conditions and at certain ages, first indicated by Thiersch. For the development of cancer it is necessary that there should be a continuous irritation, and one capable of multiplication. After the demonstration of the fact that bacteria were capable of setting up proliferative changes in the connective tissues, great efforts were very naturally made to determine whether similar organisms might not play an equally important part in setting up cancerous proliferation. Some observers thought they had succeeded, but the organisms were shown to be common saprophytic germs. We are, then, compelled to look elsewhere for an exciting agent, an agent which must act continuously in the sense that it has the power not only of persisting, but of increasing in quantity and in activity. It must also have, under certain conditions, the power of acting almost specifically on epithelial cells, and of setting up proliferation in them at the expense of their functional power. All these qualities must be inherent in the irritant that has the faculty of stimulating epithelium into cancerous activity; this we know from our observations on the nature of the disease.

It has long been known to zoologists, especially to those interested in the animal parasites, that we have a number of parasites most of which affect epithelial cells, which exhibit little motion, are more or less homogeneous in structure, but which are surrounded by a hard smooth cuticle. This class of organism has been specially described as occurring in the liver of the rabbit, where, under the name "coccidium," it is known to set up a peculiar irritated condition of the bile ducts, which ends in the formation of psorosperm nodules, which are really cysts containing papilliform projections covered with rapidly proliferating epithelium, in the cells of which are numerous protoplasmic bodies answering in all respects to the description above given. Similar organisms, setting up similar proliferative changes, have been described as present in the epithelial cells lining the intestine of the mouse, the dog, cat, rabbit, and even of man. On examining the literature and descriptions given of these parasites, and of the effects they produce, one cannot but be struck by the very marked similarity, not only as regards the naked-eye appearances, but also as to the histological changes generally (especially those that are found in the epithelium), between psorosperm nodules and cancerous growths. We have here, then, in the lower animals organisms which, as parasites of the epithelial tissues in which they set up and maintain continuous proliferation, and comply with all the conditions required, theoretically, in the irritant that should be the cause of cancer. This being the case, it was natural that in psorosperm infection, observers should look for the cause of epithelial cancers, and for long there has been a vigorous strife between those who believe that certain structures met with in the epithelial cells are merely colloid bodies and those who maintain that some of them at least are parasitic organisms which have a definite structure and play a definite part in the production of cancerous growths. An important paper was published by Russell, in which he pointed out that he was able to stain certain structures in cancerous tissues very brilliantly, and that these structures appeared to bear a definite causal relation to the growth of cancer.

With the assistance of Mr. Douglas Stanley, M.B., I have been able to examine a very large number of tumours kindly supplied to me by Mr. Hulke, and have so been able to confirm Russell's observations as regards the presence of his so-called fuchsin bodies. Russell looks upon these bodies as being probably somewhat closely related to the yeasts, and he describes in them a kind of reproduction by budding, which, he thinks, supports his contention. On careful examination of many specimens specially hardened with bichloride of mercury and alcohol, I was, however, led to believe that these bodies resembled the coccidia group more than any other known organism; in the larger ones especially, where there appears to be a distinct investing capsule, there is often a rather more deeply stained centre, sometimes granular, sometimes perfectly homogeneous, whilst the differentiation between the central portion and the periphery is frequently well marked, the central portion being irregularly mottled with small radiating projections, which may be sharp-pointed or club-shaped. Again, the protoplasm within the capsule sometimes assumes a stellate form. Wherever these larger organisms are found, small fuchsin-stained points can always be distinguished in or near the nucleus of the proliferating epithelial cells; they are quite distinct from the nucleus, and the only thing to which they can be compared is the adnuclear body. In some cases the nucleus is pushed to one side, forming a crescent around one end of the fuchsin body, whilst in other cases the nucleus has almost disappeared, and the fuchsin body appeared to be surrounded by a ring of protoplasm, the remains of the epithelial cell with a little granular matter, the remains of the nucleus, at one corner. Soudakowitch's observations, recently announced in the "Annales de l'Institut Pasteur," offer most important confirmatory evidence as to the nature of these intra-cellular organisms, important because he has been able to demonstrate the possibility of throwing these objects into much greater relief than has ever yet been done. On account of the thick chitinous capsule of the coccidium, its contained protoplasm appears to be little affected by the action of weak chromic acid or Muller's fluid, and the organism continues to live and then to undergo degenerative changes after the protoplasm of the epithelial cells has been partially fixed by the hardening reagents. By fixing the tissues rapidly with bichloride of mercury, osmic acid, Fleming's solution, or absolute alcohol, the structure of these organisms is retained, in some degree at any rate, and then, by staining with logwood or with logwood and saffranine, this structure can be brought out fairly distinctly. After examining specimens so prepared, so great an authority on zoology as Metchnikoff pronounces the organisms to be undoubtedly coccidia. Dr. Ruffer and Mr. J. H. Walker have placed at my disposal a number of sections stained with a combination of aniline dyes, some of which are under the microscope; others we have been able to photograph under a magnification of 800 diameters. A careful examination of these sections removes all doubt as to the nature of these bodies; they are certainly not the result of degenerative processes; they are not leucocytes or red blood-corpuscles taken into the epithelial cells, though small cells appear to find their way into the proliferating epithelial cells in some cases; equally certain is it that they are not vacuoles. They have, indeed, as Metchnikoff points out, all the characters of coccidia. In some of the capsules there appears to be a process of division going on, whilst here and there are capsules in which several (four to twelve) small rounded or crescent-shaped psorospermæ, in other respects like the coccidia except that they have no capsule, may be made out. In one or two instances these appear to be lying free between the epithelial cells, from which they have probably escaped on the breaking down of the mother capsule. They are of very various sizes, from the diameter of a red blood-corpuscles to three or four times that size. On examining a section of a rapidly growing secondary cancer in which these bodies are present, the proliferation of the epithelium is always most marked where the encapsuled bodies are most numerous. In the larger alveoli many of the cells contain these organisms, and in the long narrow spaces, where we have simply a single row of epithelium cells, every third or fourth cell may be seen to contain at least one, whilst in transverse sections of these spaces a single one of these bodies fills up the whole of the cavity. We are still very far from the proof that these organisms are the actual cause of cancer. Why should they make themselves felt only under certain conditions and at certain periods of life? We have already spoken of some of the conditions favourable to the production of cancer, and it may be, as Mr. Jonathan Hutchinson says in respect to the production of tubercle by the tubercle bacillus, that a special kind of soil, and one to which special kinds of manure have been added, is required for the nutrition of the psorospermæ. The conditions of parasitism are such that the healthy dry epithelial tissues are enabled to resist the attacks of even the most vigorous parasite; when once, however, their functional activity is impaired or their vitality somewhat lowered, the coccidia may find a nidus in which they may develop, secrete the products of their protoplasm, and so act on the epithelial cells, giving rise to proliferation and allowing

Digitized by Google

them to become fully developed, and thus by their irritation bringing them back to their embryonic form, during which their vegetative activity is increased in proportion to the impairment of their functional activity. It is this vegetative activity that enables them to invade the lymph spaces of the connective tissue. Beyond this, however, these same products of metabolism must exert an irritant effect on the connective tissue in the immediate neighbourhood of the proliferating epithelial cells, and so give rise to what is practically granulation tissue; the greater the departure of this from the normal fully developed connective tissue the more readily does it allow of the invasion of the proliferating epithelial cells. May not these secretions also play an important part in the cachexia so marked a feature not only in cancer, but in all cases of coccidial disease both in man and in animals? One extremely weak link in the chain of evidence is that hitherto all inoculation experiments with cancerous material have failed most signally to produce any cancerous reaction. At first sight this appears to be an almost insurmountable obstacle to the acceptance of coccidia as the primary causal agent in the production of cancer; but it must be remembered that the evidence offered by zoologists as to the nature of these organisms indicates that they are exceedingly fastidious, both as to the positions in which they will grow and the kind of nutriment they will take up.

In the inoculation experiments that have been made the cancerous mass has usually been introduced into the connective tissue, into the veins, or into the abdominal cavity; in which position, although it has been demonstrated that coccidia can retain their vitality for three days, the tissues in which they are lodged, and eventually the coccidia themselves, are absorbed by the new connective tissue that is formed around them, a small mass of such connective tissue being all that is left to indicate the locality of the inoculated tissue. As soon as the epithelial cells disappear, the coccidia have nothing on which they can subsist or in which they can grow, and they immediately undergo degenerative changes, and are removed just as were the epithelial cells. Under the most favourable conditions for their growth and development they appear to be able to continue their existence only when protected from the connective tissue by the proliferating epithelium in which they are lodged. It is little wonder, therefore, that inoculation experiments have not succeeded. A coccidial origin of cancer, if proved to be correct, would render it necessary that we should throw aside the doctrine that cancerous epithelium can be developed from anything but epithelial cells. We can, no doubt, find various kinds of epithelium, according to the seat of origin of the cancer, the rapidity with which the cells proliferate, and the extent of the invasion; but in every case we find epithelium which resembles in a greater or less degree normal epithelium. From what has already been said as to the relation of the coccidium to the epithelial cell, it is evident that, in order that a primary cancer may be developed or a secondary cancer grow, epithelium must be present in which the coccidium can maintain its existence and perform its parasitic functions. Before I conclude I wish to say a few words under my third head.

In all our researches as to the nature and etiology of cancer we have in view the alleviation of the suffering of those who are affected by this disease; and hitherto our main object has been to determine how far it was necessary to remove certain structures in order to minimise as far as possible the chance of any return of the disease. From a careful microscopical investigation of many hundreds of cancers that have been submitted to me for examination, I am firmly of the opinion that many surgeons make the mistake of not removing sufficiently freely either the tissues in which a cancerous growth has made its appearance or the lymphatic glands associated with it. Quite recently Mr. Harold Stiles, of Edinburgh, has carried on an extensive and careful investigation into the question of how far the immediate tissues around the naked-eye cancer of the breast are affected. His method is based upon the effect which nitric acid has upon the tissues, causing the connective tissue to become clearly differentiated from the epithelium. From a careful study of sections so prepared, both by Mr. Stiles and myself, as well as from microscopic examination, I am convinced that the only safe rule to be observed in removing cancer of the breast is to remove not only the main mass of the gland, but all outlying portions of glandular tissue, so that if on cutting away the margins of the tumour, treating with methylated spirit and nitric acid and then with water, any opaque columns or fragments are to be seen still, I should consider that the removal has not been free enough. Of course, the part of the tumour that should be specially examined in such a case is that near the sternum, where, on account of the shape of the incision usually adopted, as pointed out by the late Charles Moore and mentioned to me by Mr. Hulke, there is the greatest danger of fragments of the gland being left. I shall not to-day attempt to enter into any discussion as to the relative frequency of the spread of cancer by bloodvessels and by lymphatics, although latterly some doubt has been thrown on the accuracy of our present teaching in regard to this question. I will merely state that I am more and more convinced that cancer extends almost entirely by the lymphatic vessels, that this takes place not only locally by direct extension, but in some cases where the lymphatics are especially wide, and especially after they have been called upon to do temporary extra work, the cells may make their way for some distance without leaving any intermediate trace between themselves and the parent mass. It may appear that I am taking much for granted, and of which at present we have extremely insufficient proof; but I hold that until we have more definite knowledge on all these points, we must for the sake of our patients accept them as proved, and certainly take them into consideration when planning out our method of treatment.

OUR MISTAKES.[1]

BY WILLIAM MURRAY, M.D., F.R.C.P. LOND.

THE man who makes no mistakes seldom or never does anything worthy of note. Life is so closely interwoven with tentative efforts on the part of those who keep its machinery in motion, that it would be strange indeed if mistakes were not often made. As experience, often dearly bought, on the part of both doctor and patient, is our best guide amidst the pitfalls which surround us, I think it is a most profitable task to go over the ground of our past experiences and gather up the lessons taught us by our failures and mistakes. A great general was once found making a careful survey of the field of a battle which he had won. On being asked what he was doing, he said he was *studying his mistakes*—a lesson well worthy of our imitation. Our mistakes may be divided into (1) those which can and ought to be avoided by every intelligent, well-taught, and experienced practitioner; (2) those which can only be avoided by an unusual amount of experience and insight; (3) those which no amount of care, experience, or insight would enable us to avoid. I shall give examples of these as we proceed. In disease nature is for ever making fresh experiments before our eyes, and we are to watch how she varies the experiment, lest its many variations from the normal type of the disease mislead us into a false diagnosis. Each disease varies as much in expression as the human countenance. In my experience no two cases are exactly alike. What is described as a typical case exists only in the imagination of the writer of a text-book or a lecturer to his class. This typical case is like the archetypal vertebra, which exists only in the brain of the anatomist; all real vertebræ are, like all real diseases, variations from the typical. To push the analogy, just as the skilled anatomist can amplify the most rudimentary vertebra into one possessed of all its parts, so the skilled physician can grasp the true nature of a case and build up a diagnosis from the faintest indications; and, further, he can simplify and reduce to order the most irregular and complicated manifestations of a difficult case. It is by the exercise of this constructive faculty on the one hand, and by that analytical faculty on the other, that our difficulties are to be overcome and our mistakes avoided.

With regard to the first class of mistakes—namely, those which ought to be avoided,—let me remark that the best of us will sometimes be caught napping. "Nemo mortalium omnibus horis sapit." We somehow get on the wrong scent in a case, and becoming occupied by a train of minor symptoms, miss its main features; or we are the victims of

[1] An Address delivered before the Newcastle Clinical Society.

Digitized by Google

a preconceived opinion, and it shuts our eyes to facts which would be patent enough if we brought an open mind to the case. I shall give one or two illustrations of the kind of thing which occurs. There is no more common source of error in diagnosis than the subtle development of hydrothorax or empyema after an acute illness. When these diseases arise from an attack of pleurisy pure and simple there is little fear of their being overlooked—in fact, they are then often diagnosed when they can hardly be said to exist. But when they supervene on another acute illness, such as typhoid or scarlet fever, the practitioner is liable to miss their existence, and to attribute the rapid breathing, quick pulse, and fever to some other sequel, such as tubercular disease, bronchitis, or albuminuria; yet the faintest suspicion would lead to the easy detection of the true state of affairs. The immovable chest wall, the absence of respiratory sounds, the dulness on percussion and the absence of vocal fremitus, are indications too clear to be easily mistaken. The mistake arises from a want of suspicion or a want of alertness, or from a want of care in making a thorough and frequent examination of the patient.

"Strip him!" is a motto which ought to be engraven on all our minds. This brings me to another source of error; that is, the want of a thorough examination of the various canals and cavities—the mouth, the throat, the nares, the ear, the rectum, the generative and urinary tracts, &c. I need not say that I refer to an examination by all the specular aids we possess. No small number of failures and mistakes arise from inattention to this point. Let me give one or two illustrations. Whenever we are at a loss to account for high temperature, the throat should be examined. There may be a good deal of mischief there without any complaint on the part of the patient. I well remember being called to two consecutive cases—one of supposed pneumonia, the other of quasi-puerperal fever,—in each of which I found that diphtheria was the true cause of the illness. Within a very short time a gentleman called on me, with an apparently feverish cold. As he did not get well, he asked me to call on him; and I, thinking his symptoms were due to the above cause, handed him over to the care of an exceedingly acute local practitioner, who discovered at his first visit that our patient had a diphtheritic throat. Most medical men will agree that such mistakes are not uncommon, and we need to add to our first motto, "Strip him!" another equally golden rule—to examine the canals and cavities. Another illustration may be added. A short time ago I was asked to see a child suffering from obstinate hæmorrhage from the bowels, and I said at once, "I shall find a pediculated polypus in the rectum," which was found and detached at the moment. My experience at the Children's Hospital had taught me this lesson years ago.

A further illustration still occurs to me. A gentleman whose name is now a household word throughout the world called on me in great alarm on account of an attack of blood-spitting, which came on while he was dressing. I saw a good deal of blood on his handkerchief, and on examining his chest heard, or thought I heard, rough breathing and fine crepitation over the left apex. I told him this, and treated him accordingly. On going to his shop he, knowing something about dentistry, looked into his mouth, and discovered that the bleeding was from a spongy gum, which he had doubtless lacerated with his toothbrush. I need not say that he lost confidence in me, and I lost my patient. Time would fail me to make further remarks on these casual cases, where mistakes are often made for want of thought and care.

I will now relate a series of cases of cancer where a diagnosis was only to be made by an unusual amount of care, experience, and insight; and if I seem to be egotistical by taking praise or blame to myself, I trust my unintentional fault will be pardoned. I am going almost entirely on my own experience, and I am thus compelled to speak of myself oftener than I like. Cancer of the internal organs rarely fails to puzzle us at the outset, and a diagnosis is seldom made until the disease has made considerable progress. In the absence of distinct physical signs, and with only subjective symptoms, such as pain, to depend on, we are very liable to be landed in a grave difficulty of diagnosis. If we suggest there is, or may be, malignant disease, the responsibility is great; if we risk an opposite opinion the responsibility is equally great, as the sufferings of the patient are often urgent and demand an explanation. Mistakes can only be avoided here by the utmost caution and the most watchful investigation. There is, however, one feature about these cases which occurs to me when I look back on a long series of them. It is this, that most of them have given at a somewhat early period just the faintest hint of what is going on. I have often felt too late that a wise interpretation of this or that faint hint would have saved me and others from the ignominy of being forestalled in our diagnosis by someone else. It is easy to name a full-blown flower, but difficult enough when that flower is in the bud. I shall now give an experience founded on five cases of internal cancer, which will illustrate my meaning.

Some years ago a case occurred in the practice of the late Dr. Douglas of Gateshead, in which the chief, and for a long time the only symptom was pain in the tibia. The man was emaciated and suffered intensely. He was seen by two or three physicians and one or two leading surgeons. None of us could form a diagnosis. There was no swelling, heat, tenderness, or alteration in the shape or appearance of the limb. At length some softness and shining of the skin marked the seat of pain, and even then grave doubts were entertained as to the nature of the disease. Within a few days of his death I was called to see him again, and I found he had expectorated some currant-jelly-like matter; but even this failed to suggest a true diagnosis, and so the man died of "no one knew what." Meditating on this case, it all at once flashed into my mind that the red-currant-jelly expectoration was a hint of the true nature of the case, and that the man had doubtless died of cancer of the lung, following or accompanied by malignant disease of the leg. I felt that a serious error by default of diagnosis had occurred, and was much humiliated thereby.

Not long after this I was called to see a case in Weardale, and was told on arrival that the patient was suffering from congestion of the lungs. The expectoration, which was shown me before I examined the patient, at once convinced me that this was a case of cancer of the lung. There were, however, no physical signs; and on mentioning my conviction to the medical attendant he was very sceptical, and threw on me the enormous responsibility of giving an opinion based on the one isolated fact of currant jelly expectoration. I therefore re-examined the chest and discovered a cancerous nodule in the right mammary gland, which of course set the diagnosis at rest. An unfavourable opinion was given, which soon afterwards proved mournfully correct.

A short time after this I was called, with my friend, Dr. Adam Wilson, to see the married daughter of the above lady. We were informed that her arm had been amputated above the elbow by Sir Joseph Lister for disease in the forearm. The patient was then complaining of pain at the posterior base of the right lung, but the physical signs were faint and doubtful. We therefore reserved our opinion, but privately agreed that it was probably a case of cancer of the lung, and that Sir Joseph Lister had amputated high for malignant disease of the forearm. In due time came the currant-jelly expectoration, and she died of cancer of the lung. In these cases the faintest hints were given at the outset, and errors by default of diagnosis could only be avoided by paying heed to them. We ought to make ourselves well acquainted with this red- and black-currant-jelly like expectoration of cancer of the lung so as to be able to distinguish it from the bistre or sooty tint of pulmonary apoplexy and old hæmoptysis.

Pursuing this subject, two other instructive cases occur to me. About fifteen years ago the late Mr. Manford had a case which puzzled several of us. The chief symptom in this case, for at least six months, was an intolerable pain on the front of the right thigh three inches above the knee-joint. All sorts of opinions were expressed, and of course hysterical knee was the favourite. At last it occurred to me that, this region being supplied by terminal twigs of the obturator nerve, we ought to examine that nerve along its whole course, and this could only be done per rectum. On passing the finger the secret was at once discovered to be a carcinomatous mass springing from the side of the pelvis, and growing into that part of the pelvic cavity which is traversed by the obturator nerve.

(To be concluded.)

REMARKS ON THE

STATE OF THE VESSELS OF THE PIA MATER IN BRIGHT'S DISEASE ("ARTERIO-CAPILLARY FIBROSIS").

BY A. G. AULD, M.D.

(From the Pathological Laboratory of the Western Infirmary, Glasgow.)

IN the course of the past eighteen months I have examined the vessels of the pia mater in all (or nearly all) brains removed for examination in the post-mortem room of the infirmary during that period. In each case the pia mater was hardened for a long time in Müller's fluid, and afterwards in alcohol. The method adopted for examining the coats of the vessels consisted in washing out the alcohol, soaking in gum and sugar solution for a few days, then freezing the membrane *en masse*, and cutting sections. It cannot be said that the resulting sections were the best that could be desired from an artistic point of view; but after careful staining and mounting, I have made out by means of high powers what appears to be the true nature of the "hyaline-fibroid" thickening of Gull and Sutton. As is well known, these authors, in their celebrated papers, contended that in chronic Bright's disease the vessels throughout the body generally, and especially those in the pia mater, had their outer coats thickened by a "hyaline-fibroid material," while the muscular coat showed atrophic changes, and the tunica intima was generally unaltered, though occasionally thickened. With respect to the muscular coat, such an atrophy has generally been denied, and Johnson especially laid stress on a true hypertrophy of this layer, quite apart from any question of an *apparent* hypertrophy from contraction occurring at death. On the other hand, all observers are agreed as to a thickening of the outer coat. First, as regards the larger vessels, my observations go to show that in Bright's disease (though not limited to this affection) a hypertrophy of all the coats is the condition most generally observed, and of the three, that most frequently excepted from hypertrophy is the inner, while that most constantly involved is the outer. The thickening of the inner coat consists in an endarteritis, such as forms the first stage of atheroma, causing the intima to be represented by a more or less thick and unequal layer of very cellular tissue—a tissue produced by a rank cellular proliferation. This was very characteristic of cases presenting the atrophic stage of large white kidney, and was not so pronounced in cases of ordinary granular kidney. As regards the muscular layer, in most of the cases there was undoubted increase of the muscle nuclei. There was then always hypertrophy of the left ventricle of the heart. In a few cases the muscular layer showed a degree of atrophy, unequally distributed, and some fatty degeneration of its cells; there was then usually some fatty change in the heart. Occasionally not much alteration from the normal was detected. With respect to the condition of the outer coat, as stated, all observers agree that this coat is thickened, and sometimes very greatly so, in the cases under consideration. It presents in the arteries and arterioles alike a homogeneous, somewhat translucent, aspect, which in the larger vessels is particularly marked in that portion which lies nearest the muscularis. Gull and Sutton held that there was a deposition or formation of a "hyaline-fibroid" substance, giving this coat the appearance described by Dickinson, "as if swollen with translucent structureless exudation."[1] Johnson and others considered this hyaline appearance to be a delusive result of reagents—e.g., glycerine, acidulated mounting fluids. In any case, the cause of the hyaline-fibroid formation has not so far been determined. Now I have invariably made out by means of oil-immersion objectives (Zeiss) the existence of branched corpuscles with large and frequently divided nuclei embedded in this hyaline-fibroid substance. Further, after maceration in picric acid and exerting pressure over the cover-glass this homogeneous-looking layer was seen at the cut extremity of the vessel to be split up into exceedingly fine fibrils. In short, it was clearly demonstrated that this formation is ordinary connective tissue derived from connective-tissue corpuscles after the manner of inflammatory tissue. And not only in the outer coats of the vessels, but likewise throughout the whole tissue of the pia mater, this corpuscular change was usually seen, leading to a more or less general thickening.

From these observations it is to be concluded: 1. The hyaline-fibroid thickening of the outer coat of the vessels is not of the nature of an exudation or deposition of a foreign substance, nor yet a transformation of existing structures. 2. The effect of reagents is, after all, but unimportant. 3. The thickening of the outer coat is unquestionably due to proliferation of connective-tissue corpuscles embedded therein, leading to new formation of tissue; in short, is a slowly progressing periarteritis. 4 This change is probably general throughout the entire tissue of the pia mater. 5 The muscular and inner layers of the vessels show hyperplastic changes at first; latterly atrophic and degenerative changes set in.

In the case of the smaller arterioles their muscular elements were certainly increased in volume, if not also in number, and their delicate investment of connective tissue was represented by a thick, homogeneous-looking cylinder. It is particularly to be noted, however, that their endothelial lining showed no deviation from the normal, in this respect presenting a marked contrast to the condition prevailing in the larger vessels. The diameter of the channels in these thickened arterioles suffered great diminution; not infrequently it measured just the diameter of the wall. Such a diminution suggests an adequate explanation of the cardiac hypertrophy in chronic Bright's disease. I hope, however, to return to the consideration of this point.

In conducting these observations, I may say that it was impossible not to be struck with the marvellous advance made in this department of pathology by the distinguished authors of "arterio-capillary fibrosis."

PLACENTITIS AND MISCARRIAGE.

BY CHARLES GAYFORD, M.D. DUR., M.R.C.S., &c.

THIS case is one of more than ordinary interest, and will doubtless be of service to other members of the profession.

On Feb. 13th I was summoned hastily to see Mrs. C——, whom I found seated on a commode in which was lying a fœtus of about five months. She said the expulsion had come on quite suddenly, though she had been ailing for some weeks. The following history was elicited. On Boxing-day she had shivering and great headache, but she did not go to bed. A day or two after, while still feverish and in some pain, she came on unwell, and lost freely for two days, more than at ordinary monthly periods. The loss then lessened, and she, still keeping about, thought she must have made a mistake in her opinion as to pregnancy. A second loss occurred a few days subsequently, followed by a very copious discharge of "whites." Still she kept about, though often feeling extremely ill and unfit for her duties, which were those of a matron of a boys' home. In this way some five weeks passed before the mishap occurred for which I was called in, and during this time she had only once seen a doctor. She had all the time been in failing health. On my arrival I severed the cord, which was bloodless; and the fœtus, which was discoloured, had probably been dead several days. There was no trace of any membranes, nor was there any evidence of amniotic fluid. After getting the patient on to the bed I examined her for the purpose of removing the placenta. I could trace the cord up to the point of attachment on the uterine wall, which presented at that point a puckered, rough, and somewhat hard surface, but no further evidence of the presence of a placenta. After waiting a little time for uterine contractions to come on, as I had given ergot, I made a further attempt to get the placenta away, but in vain. The cord was firmly attached, and any force seemed likely, owing to the condition of inertia in which the uterus was, to bring about prolapsus, if not inversio uteri. I left my patient for a time, with orders to call me at once if any need arose. After an interval of an hour I saw her again, when the same state of things was found. There had been no pains and there was no hæmorrhage, nor had the cord become detached. After giving another drachm

Digitized by Google

dose of ergot I left, giving instructions to be called at once if necessary. This time I was two hours away before calling, and when I arrived found a considerable amount of hæmorrhage. I emptied the uterus, removing several clots, which were small and all carefully examined, and in doing so, without using any but the gentlest traction, the cord got released from its attachment and came away. It showed evidence of attachment to what had been placenta merely. It was spread out to about the size of a two-shilling piece. Its attachment showed nothing more than a spreading out of the outer covering of the cord; there was no evidence of membranes or any portion of placenta attached to it. There was the same condition of uterine wall. The hæmorrhage ceased, and I left my patient, to be seen again later in the day. I ordered the use of an injection of 1 in 5000 bichloride of mercury solution and a mixture of bromide of potassium and liquid extract of ergot. The next day her temperature was 100·2° F., but it went back to normal in the evening and remained so during the whole of the convalescence, which was uninterrupted. I allowed her to get up on the fourteenth day, and she has since been about as usual. There was no placenta discharged, no hæmorrhage after the one I have spoken of, nor any ill-smelling discharges. At the month after the occurrence she had a slight flow, but nothing to speak of, for two days. At the next period she lost freely for three days. She has resumed and still continues her somewhat arduous duties, and is in good health.

My diagnosis in this case was miscarriage following placentitis. My belief is that she had influenza the week after Christmas, and that this set up the trouble. This is her fifth pregnancy. There is no evidence of specific mischief, though she has been singularly unfortunate. Two of four children were born at full time dead. Shoulder presentations. The others were one shoulder and one breech presentation, both of whom are living and healthy children. Both parents are young people and healthy. I should be glad to hear of any similar experience, for my own feeling is that the evil effects of the so-called influenza show mischievous ramifications so widespread that hardly any portion of the body can claim immunity from its ravages.

Fleet-street, E.C.

ACUTE INTESTINAL OBSTRUCTION; OPERATION BY SHORT CIRCUIT.[1]

BY EDWARD ATKINSON,
SENIOR SURGEON TO THE LEEDS GENERAL INFIRMARY.

G. F——, aged twenty-two, was admitted into the General Infirmary, under Dr. Churton, on Wednesday, Nov. 25th, suffering severe pain in the right side of the abdomen. In Dr. Churton's absence Dr. Jacob asked me to see the patient with him, when the following history was elicited:—Nine days previously he was seized with severe pain in the epigastrium and right side of the abdomen. He left his work and remained at home two days, taking castor oil and other medicines, which were vomited, together with all the food that he took. The third day, feeling better, he went to work again for two days, when the symptoms returned, and on Friday, the 20th, he kept his bed. The next day acute pain came on and vomiting, nothing having passed the bowels for some days. On the Sunday he passed a small motion and felt somewhat better for it, but on Monday the pain and vomiting returned, and lasted without intermission till his admission on Wednesday afternoon (the 25th), and no more motion had passed. On examination the abdomen was tense and tympanitic, especially on the right side. The patient complained of pain of a sickening character right across the hypogastrium, and he had manifest tenderness on pressure over a limited area in the right iliac region. There was resonance over the whole abdomen, and the movements of the small intestine could be distinctly seen. The patient said he had passed a little flatus in the morning, but two enemata given him after being admitted into hospital had not been followed by any further relief. The symptoms seemed partly to point to the cæcum or vermiform appendix, but the vermicular movement of the small intestine suggested that the obstruction was higher up. However, the fact that he had had no opiate, and his statement of having passed a little flatus, induced me to order a hypodermic injection of morphia, as it was late at night, and to wait till the morning. The next day he was no better, and so I resolved to explore. At 10 A.M., under chloroform, I made an incision five inches long over the outer border of the right rectus muscle. On opening the peritoneum a quantity of clear fluid escaped. Nothing suggestive of typhlitis or perityphlitis was found, but distended coils of small intestine presented at the wound. These were united to one another and to the iliac fossa by broad bands of adhesion, not recent, and prevented my being able to draw them forward or trace their course. These bands were evidently not the cause of obstruction. Being unable to see or feel any large intestine, I carefully tied and divided one or two of the broad bands, which enabled me to turn aside a coil of small intestine, and then found the cæcum behind it empty. It being now evident that the matting of the bowels rendered any further search for the cause of the obstruction impossible, the only course which seemed available was to bring the small intestine out of the wound and make an artificial anus; but Mr. Littlewood, who was present, suggested to me that the expedient of short circuiting, which he had performed in the case which he read to the Society a fortnight ago, would be equally applicable here. Accordingly I opened the collapsed colon, as much above the cæcum as I could reach, and inserted a Senn's bone plate; and after isolating the nearest coil of ileum, and securing it by tying a piece of indiarubber tubing round it, I opened it and inserted the corresponding plate. The large and small gut, being now brought into apposition, were further secured by marginal sutures around the plates, and the peritoneal wound was closed with deep silk sutures and silkworm gut for the external wound. Altogether the operation lasted an hour and a quarter. Within twelve hours after the patient had two large liquid motions, and next morning he expressed himself as feeling quite comfortable. His recovery has been uninterrupted, except for an abscess in the abdominal wall about a week afterwards, which soon cleared up. He was kept without food for three days, then small quantities of milk were allowed, and in a week afterwards he took rice pudding and mincemeat, and is now on ordinary diet.

It will readily be seen how immense an advance this procedure offers in the treatment of those cases of acute obstruction where the cause is, after careful search, either undiscovered or out of reach; and which otherwise would have to be relegated to the category of incurable cases, or dealt with by the formation of an artificial anus. With this new departure one may hope that few cases of obstruction will arise in which relief is unattainable, if treated in time.

Leeds.

[1] A paper read on Dec. 18th, 1891, before the Leeds and West Riding Medico-Chirurgical Society.

A CASE OF

SECONDARY CANCER OF THE RIB, VERTEBRÆ, AND OVARY,

OCCURRING AFTER REMOVAL OF THE PRIMARY DISEASE IN THE MAMMA, AND COMPLICATED BY MYOMA OF THE UTERUS.

(From the Pathological Laboratory of the Glasgow Royal Infirmary.)

BY JOHN LINDSAY STEVEN, M.D.,
PATHOLOGIST, GLASGOW ROYAL INFIRMARY;
AND
JOHN BROWN, M.D.,
DISPENSARY SURGEON, GLASGOW SAMARITAN HOSPITAL FOR WOMEN.

THE following case is of interest as affording an illustration of the recurrence of mammary cancer in the bones. It is unfortunate that no accurate and exhaustive clinical record of the earlier period of the case is now possible, as the operation was performed at the patient's home, and I have been able to obtain only very meagre information as to the opinion held at the time regarding the nature of the primary tumour.

Mrs. C——, aged forty-six, housewife. The patient has had two children, both delivered by instruments; the last,

Digitized by Google

born in 1872, died soon after birth. Menstruation has always been normal in quantity, regular, and without pain up to September, 1890, when it ceased. In May, 1889, the right mamma was removed by Mr. H. E. Clarke for malignant disease. She was admitted into the Royal Infirmary, Glasgow, on Feb. 16th, 1891, with the following symptoms: Extreme constipation, no passage of fæces by bowel being obtainable without an enema; no appetite; the constipation and loss of appetite dating from August, 1890. She complained of severe pain in the left lumbar region, which had commenced in September, and also pain on the outer side of the left thigh, which she compared to cramp. In December the left leg became paralysed. Before her admission to hospital a tumour in Douglas's pouch was diagnosed as attached to the body of the uterus posteriorly. Operation was refused, and she was dismissed from hospital on Feb. 25th. She was readmitted on Jan. 11th, 1892, with all the above symptoms. During the past three months the urine required to be drawn off by catheter. An exploratory incision was made on Jan. 31st, and as the uterine tumour did not account for all the symptoms, nothing further was done; but the incision closed, and the patient died the following day. The family history was unimportant.

Necropsy.—The body was that of a woman apparently about fifty years of age, much emaciated; pupils equal and medium; rigor mortis passing off; abdomen deeply discoloured, and a sutured incision extended from a little above the pubes almost to the umbilicus. Nothing remarkable was noted in the cicatrix of the mammary operation. On opening the thorax, the pericardium was found to contain a couple of ounces of deeply blood-stained fluid. The lungs were non-adherent and fairly voluminous. With the exception of a slight catarrh of the bronchi and a slight emphysema of the anterior borders, both lungs appeared healthy. The right lung weighed nineteen ounces, the left sixteen ounces. The aortic curtains were competent; the lining of the heart and great vessels were deeply stained with blood-colouring matter. The heart muscle was fairly firm, but the heart was small, weighing eight ounces and a half. The abdomen contained a large quantity of opaque brick-red fluid. The coils of intestine appeared healthy. The spleen was healthy, weighing four ounces and a half. Both kidneys were somewhat congested, but otherwise healthy (the capsules were easily removed); the left weighed five ounces and a half; the right four ounces and a half. The liver showed a slight amount of fatty infiltration, but appeared otherwise healthy; it weighed forty-five ounces. The mucous membrane of the stomach, except a slight amount of congestion near the cardiac extremity, was healthy. The left ovarian vein was very large and convoluted. The vena cava inferior was enormously distended. On removing the great vessels from the front of the spine a distinct prominence of the second lumbar vertebra was noticed. On sawing out a wedge-shaped piece from the bodies of the vertebræ, the first and second lumbar vertebræ were found to be extensively diseased. A tumour about the size of a small hen's egg was found protruding into the thorax from the third right rib about two inches external to the spine. The rib in the neighbourhood of this tumour was very friable and the tissues around much congested. On removing the pelvic organs a tumour was discovered in the posterior surface of the uterus; it had a broad base, being attached to nearly the whole of the posterior surface, the only portion free being the space of about half an inch between the fundus and the tumour. The tumour was about the size of a large walnut. A hard nodule was found on the outer end of the left ovary, about the size of a horse bean. The brain and spinal cord were not examined.

Microscopic examination.—The histological relationships of this case are of a most complicated and rather confusing description, especially in view of the circumstance that the primary mammary tumour is said to have been a sarcoma—a diagnosis which the present research seems on the whole to disprove. The nodule in the left ovary presents the characters under the microscope of an acute scirrhus; in some places the alveolar stroma with the contained cancer elements are very typical; at other parts, and probably most commonly, the corpuscular elements are not so clearly in regular alveoli, but are arranged in irregular branching columns separated from one another by a fibrous tissue with many spindle-shaped nuclei. On examining the tumour of the rib it is found to consist of a highly corpuscular mass, the corpuscles being similar in character to those observed in the ovary; but the new growth in the rib differs from the ovarian chiefly in the circumstance that the stroma is much less abundant. At some places the similarity of the costal tumour to the ovarian in respect of the arrangement of the cancer elements in branching columns is sufficiently striking. In addition to the cancer corpuscles, here and there enormous collections of red blood-corpuscles are observed, which, on careful consideration, are regarded as extravasated. The naked-eye characters, as well as the histological, are indicative of very active proliferation. After decalcification the nodules of the vertebræ are examined, and are found to present a typically cancerous structure, well-formed alveoli, with cancer elements, being abundantly present. The uterine tumour is obviously a myoma, and has no relationship to the cancerous disease. It is clear that the nervous phenomena of this case were due to the involvement of the spinal column in the malignant disease, and to pressure upon the nerve trunks of the lumbar plexus &c. It is interesting also to find a secondary cancerous nodule in the ovary and a simple myoma in the uterus.

Glasgow.

NOTE ON

CERTAIN MODES OF TREATMENT WHICH INTERFERE WITH THE DIAGNOSIS OF SYPHILIS.

BY ARTHUR COOPER,

SURGEON TO THE WESTMINSTER GENERAL DISPENSARY.

THE earlier phenomena of acquired syphilis, when not interfered with by inappropriate treatment, are for the most part regular in their development and easy of diagnosis; and when difficulty and doubt do arise, if we put aside conditions due to some peculiarity in the patient himself, the most frequent cause, as far as I have been able to judge, is one or more of these three things:—1. The application of irritants (chiefly nitrate of silver) to a doubtful sore. 2. The application of irritants (chiefly iodine paint) to the groins. 3. The untimely administration of mercury. As all these modes of treatment are not uncommonly employed, and as they are all capable of giving much unnecessary trouble to the doctor as well as to the patient, I would venture briefly to state some of the reasons why they should be avoided. The application of nitrate of silver to a sore of uncertain nature, apart from the unnecessary pain and irritation produced by it, is more especially to be avoided because it is so liable to cause inflammatory hardness which may be either itself mistaken for syphilitic hardness, or may mask true syphilitic hardness. Irritation of the skin over inflamed glands is to be avoided for two reasons: First, because suppuration may be induced; and secondly, because so much infiltration and hardening of the skin and cellular tissue may be set up as to hide the enlarged glands of syphilis, if that disease has been contracted. Mercury should not be given while the diagnosis of a venereal sore remains in doubt, because the drug may either so modify the early signs of syphilis as to render them difficult to recognise, or perhaps may even prevent some of them altogether.

In illustration of these points, let us suppose such a case as this, which fairly represents a state of affairs not infrequently met with in practice: A man acquires a venereal sore. Perhaps he is married, or for some other reason is most anxious that—as he expresses it—"something should be done" at once. Unfortunately, this something often means the vigorous application of a stick of nitrate of silver. This sets up irritation and inflammation, and, if the situation of the sore be favourable, often phimosis as well. Then some enlargement and tenderness of the inguinal glands probably follows. Now something else has to be done, and this further something usually consists in a liberal use of iodine paint to the groins. The irritated glands may resent this by suppurating, or, on the other hand, infiltration and hardening of the superficial tissues may ensue to such an extent that it becomes impossible to say what may be the condition of the glands beneath. The patient by this time has probably become convinced that he is suffering from the worst possible form of disease, and

Digitized by Google

he urgently demands that mercury should be begun "as a precaution," or "to be on the safe side" as he puts it. The treatment up to this point having been merely local, its mischievous effects are usually only temporary, though it may entail careful watching of the patient until the extreme limit of the incubation period of syphilis has been passed. But if the demand for mercury be satisfied, the true nature of the case may be permanently obscured. Let us assume for the moment that the original lesion was a simple one, and that there is no syphilis. By-and-bye, the irritation having subsided, the sore heals, the glands subside, and the whole thing is at an end. But if mercury has been given it is very difficult to be sure of this, bearing in mind the remarkable rapidity with which syphilis in some cases is influenced by the drug. Supposing, on the other hand, that syphilis has really been contracted, that the induration of the initial lesion has been hidden by the inflammatory hardness produced by the nitrate of silver, that the characteristic adenopathy has been hidden beneath the effects of the iodine paint, that both these important signs have been further affected by the mercury, and that the same potent remedy has also prevented, delayed, or so modified the early rash that it, too, becomes unavailable as a trustworthy aid to diagnosis. The natural consequence of all this is a state of muddle which is complete for the time, and, worse still, one which may never be cleared up. By this time the patient is probably getting a little tired both of the treatment and of the state of uncertainty as well. And as, thanks to the mercury, which has been taken in quantity sufficient to check, but not to cure, the disease, nothing definite appears at the time, he imagines himself cured, leaves off treatment, dismisses the whole affair from his mind, and gets married. Then probably the next thing is an outbreak of syphilis in the wife or child, or both, and perhaps later signs in the patient himself. But even if none of these things actually happen, a time usually comes sooner or later when he thinks of marrying, and seeks an opinion as to whether he may safely do so. The history he is able to give is, of course, worse than useless, for it is confusing; and if there happen to be nothing discoverable about the patient's body to assist the diagnosis, it may remain uncertain throughout his life whether he has had syphilis or not. The consequence is, he is afraid to marry; or, if he does marry, he is perpetually haunted with the fear of infecting his wife, or of having "tertiaries" himself, or of becoming the father of a spotty, snuffling infant.

I have by no means exhausted the list of disasters for which the modes of treatment in question may be responsible; but probably enough has been said to show cause why they should be abandoned. If this were done, there can be little doubt that the number of obscure cases of syphilis would be considerably diminished.

Old Burlington-street, W.

CITY OF LONDON LUNATIC ASYLUM AT STONE.—The report for the year 1891 states that the health of the patients had been good. The death-rate, as for some years past, was abnormally low—viz., 4·34 per cent. of the number under treatment, against 8·19 in other asylums. With regard to receiving private patients, it was deemed desirable that facilities should be afforded to persons resident in or near London, to place in the asylums any affected members of their families, and a resolution had been adopted to admit private patients for a guinea a week. The expenditure for the year amounted to £17,400.

A COTTAGE HOSPITAL FOR FALMOUTH.—The report of the subcommittee with reference to the establishment of a public cottage hospital in this town was last week submitted to the committee and subscribers of the Falmouth Dispensary. The report stated that it was desirable such a hospital should be provided for Falmouth and the neighbourhood in connexion with the dispensary, to accommodate six beds to commence with. The resident medical practitioners were generally favourable to the proposal, and would render gratuitous medical services to the poor. The estimated cost of maintaining the hospital was £200 per annum. Upwards of £500 was in the hands of the Dispensary Committee, and consequently there would be no difficulty in securing the building. It was resolved to call a public meeting, with the view of raising the necessary funds for carrying on the proposed hospital.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

METROPOLITAN HOSPITAL.

CASE OF DIABETES MELLITUS; SLOUGHING ABSCESS OF HAND; CARBUNCLES; PYÆMIA; DEATH; NECROPSY.

(Under the care of Dr. A. HAIG and Mr. WALSHAM.)

THE effect of ordinary inflammation on tissues whose vitality has been lowered by diabetes is well emphasised by this case. Gangrenous and phagedænic ulcerations take the place of slight inflammations or small, quickly healing abscesses, in healthy tissues. The destructive processes pass through the stages of inflammation, abscess, molecular gangrene, and sloughing, and it is interesting to observe that, as in this case, there is a point at which, owing to the extremely low vitality of the tissues, even necrotic changes cease. The condition of the right lung was peculiar, and, though there were no infarcts or abscesses in the other lung, or in any other organ, it was suggestive of pyæmia; and, considered in conjunction with the temperature charted during the last week of life, justified that diagnosis. The empyema might be part of the same pyæmic process. Though the case was regarded as hopeless from the first, it is probable that, but for the pyæmia, the diabetes might have been held in check and life considerably prolonged. It is worth notice that a considerable diminution of the proportion of sugar as to urea took place while the patient was taking salicylate of soda. A similar result under the same treatment was obtained by Dr. Haig in some interesting cases reported by him in the St. Bartholomew's Hospital Reports, vol. xxv., though in the case under consideration it is doubtful whether the diminution was not due to the high temperature. Certainly drugs had not a fair chance under such desperate circumstances. For the account of this case we are indebted to Mr. R. Fraser Standage, house physician.

N. T——, aged eighteen, a servant girl, came to the out-patient room of this hospital on Jan. 17th, 1892, complaining of a painful swelling on the dorsum of the right hand. She described the swelling as of fourteen days' duration, but knew no cause for it. She also complained of lumps at the back of the neck, which she had noticed for a week. The swelling of the hand—an abscess—was incised and boracic fomentations applied. She reported herself again at the hospital, and as the resulting sore did not do well she was admitted.

On admission, in the cleft between the third and fourth fingers a sloughy, ulcerated wound, leading to an abscess cavity over the dorsum of the hand, was found. The cavity extended about 1½ inches over the dorsum of the hand but not into the palm; it discharged thin, foul pus and some sloughy tissue. The edges of the opening were ragged and undermined. No bare bone was felt. On the nape of the neck was a fluctuating swelling about the size of a pigeon's egg, covered with thin, red skin, with very slight induration around it. Behind the right ear was a similar swelling, which had burst and was discharging foul sloughs and thin pus similar to the discharge from the sore on the hand. The girl was emaciated, the skin dry and harsh, and it was deemed advisable, before any further surgical treatment was adopted, to have her medically examined. This was done, with the result of eliciting the following further facts. Twelve months before admission she noticed that she passed an abnormal quantity of urine. This has continued to the present time. She next noticed that her skin became dry and

Digitized by Google

itching, and she began to suffer abnormally from thirst. Lately, she has lost flesh rapidly and has been much troubled by muscular exhaustion, being often quite unable to do her work. She has suffered from pruritus vulvæ, and is obstinately costive. She gives no history of hæmatemesis.

On examining the chest, resonance was found impaired in front at the right apex. Breath sounds were louder at the right apex than at the left. There were also bronchophony and whispering pectoriloquy, but no abnormal signs behind. Heart sounds were well heard through the extremely thin chest walls, but no murmur. Abdomen: No definite swelling was made out, but the intestines were distended with flatus. The edge of the liver was not felt below the costal cartilages. Legs: There was slight œdema over the tibiæ. Urine: The amount passed in twenty-four hours was 108 oz.; sp. gr. 1033; acid; thick cloud of albumen. An examination of the urine made after removing the albumen by boiling and filtering gave: urea 95 per cent., total 472 gr; sugar 5 per cent., total 2494 gr.; proportion of urea to sugar 1 to 5·2; amount of sugar per oz. urine 23·083 gr. The hand was treated with a continuous hot boracic bath, and with fomentations for six days, but the ulceration became more phagedænic. Further incision was made dorsally, and iodoform dressings applied. The patient was put on a suitable diet and took a pill containing half a grain of powdered opium three times, and a draught containing fifteen grains of salicylate of soda four times daily.

Jan. 30th.—The swelling on the nape of the neck burst, discharging thin, foul pus, like the other sores, through several openings. These discharging sores, which now resembled carbuncles, were treated with boracic fomentations frequently changed. Another swelling formed on the neck above the first one. Chest: The dulness has extended downwards from the right apex to the third rib in front, and over all this dull area bronchial breathing, moist rales, and bronchophony are heard. A further estimation of the urine showed a slight increase in the percentage of urea, though there was still much albumen. Amount passed in twenty-four hours 160 oz.; sp. gr. 1035; acid; urea 1 per cent., total 739 gr; sugar 5 per cent, total 3696 gr.; proportion of urea to sugar 1 to 5. The general condition was worse, there being now fever of a hectic type, the morning and evening readings showing a difference of from 2° to 4°. The emaciation was extreme and the thirst constant and distressing.

Feb. 3rd.—Ulceration of hand ceased, and the carbuncles on the neck have improved and are cleaner, most of the sloughs having separated. Urine: Amount in twenty-four hours, 106 oz; sp. gr. 1032; acid; a thick cloud of albumen; epithelial casts; urea 1 per cent, total 489 gr.; sugar 4·2 per cent., total 2048 gr. This showed a relative decrease in the amount of sugar passed. Temperature at night 103°.

4th.—Had a sudden attack of pain over the right side of the chest; breathing became very laboured, and the movements of the right side on respiration were diminished. There is absolute dulness on the right side in front below the third rib, resonance being impaired above it; also absolute dulness in the right axilla below the fifth rib. Breath sounds are inaudible over the dull area. Some pleuritic friction sounds over the upper part of the dull area can be heard; breathing distant over the right apex. Patient is very collapsed, pale, and comatose. Pulse 108; scarcely perceptible. She gradually sank, and died comatose on Feb. 5th.

Necropsy by Dr. HAIG (Feb. 6th).—External appearances: Extreme emaciation. Sores as detailed above. Brain: Meningeal vessels congested. Nothing abnormal in the brain substance; no excess of fluid in the ventricles. Chest—right lung: Costal and visceral pleura covered with recent lymph. There was about a pint of pus in the pleural cavity; no changes at the extreme apex, but the rest of the upper lobe was completely disorganised, with infarcts at the anterior border. A cavity the size of a walnut, about an inch and a half below the apex, contained thin, foul pus. No connexion existed between this cavity and the pleura. No tubercle. The left lung and heart were normal. Abdomen: The kidneys were congested, dark in colour, cortex indistinct, capsule not adherent; no pyelitis. The bladder was not hypertrophied. Liver: Dark in colour, enlarged, and firm in texture.

ROYAL PORTSMOUTH HOSPITAL.

CASE OF HERNIA STRANGULATED IN THE UPPER PART OF THE INGUINAL CANAL; ABDOMINAL SECTION.

(Under the care of Dr. WARD COUSINS.)

THIS was one of those comparatively rare examples of intestinal obstruction due to hernia in which no evidence of protrusion could be found at any of the ordinary sites of hernia. Dr. Ward Cousins has expressed his opinion of the occasional value of this method of operating by abdominal section for diagnostic purposes in some cases, and as a means whereby additional aid may be permitted in some complicated cases. Our readers will remember the discussion on median abdominal section for hernia which took place at the meeting of the British Medical Association of last year in the section of Surgery, over which Dr. Ward Cousins presided. For the report of this case we are indebted to Mr. T. H. Bishop, M.B., house surgeon.

P. G——, aged fifty-one, a blacksmith, was admitted into the Royal Portsmouth Hospital on the morning of Feb. 15th, 1892. He was suffering from internal obstruction, with collapse and urgent symptoms of peritonitis. The history was as follows:—He had been ruptured for twenty years, and was in the habit of wearing a truss. On the evening of Feb. 11th, after a fit of coughing he found his hernia had come down to a greater extent than ever before. He attempted to reduce it, but had considerable difficulty. After trying for half an hour he was successful, but he stated that he had to use some force, suffered pain, and that when the hernia did go back reduction seemed to be sudden. From this time intestinal obstruction was complete. He was seen by a doctor late on the night of Feb. 14th, who, finding signs of peritonitis, with stercoraceous vomiting, ordered his immediate removal to the hospital. On examination the rectum was found empty, and the inguinal rings and other usual sites of herniæ appeared free. Injections of warm oil with turpentine were employed, but failed to give relief to the obstruction. Dr. Ward Cousins then decided on abdominal section, as, owing to the urgency of the symptoms, exploration held out the only hope of relief. Accordingly the patient was put under chloroform, and a small incision made in the median line. On introduction of the finger into the abdominal cavity a knuckle of kinked and adherent bowel was found in and around the upper part of the right inguinal canal. This was released and examined. The abdominal cavity was then washed out with warm water and the wound closed. The patient survived the operation nearly three days, dying on Feb. 18th at midday. No fæces were passed after the operation, but on several occasions flatus was. Signs of peritonitis were well marked. Post mortem nothing was found beyond general peritonitis. The portion of bowel released at the operation was recognised by its dark colour.

Remarks by Dr. WARD COUSINS.—Unfortunately, surgical aid in this case occurred too late. Strangulation had existed several days, and at the time of the operation peritonitis was well marked, attended by intestinal paresis. The hernia had been incompletely returned by the patient himself. Over and over again he had successfully manipulated it when it had slipped down behind his faulty truss. It is very probable that chronic inflammatory changes had recently taken place around the neck of the sac, and a portion of the intestinal surface had become adherent around the internal ring. At the time of the operation the inguinal canal appeared to be empty, and I regarded the accident as a reduction in mass or a strangulation returned with constricting bands at the neck of the sac. The case was clearly one for treatment by median abdominal section after the method advocated by Mr. Lawson Tait, for relief would have been impossible by any other procedure. A small portion of collapsed intestine was found partly kinked within the canal and partly adherent around the orifice. The operation was both easy and simple, and by gentle exploration with two fingers an accurate diagnosis was made and the cause of the obstruction easily removed.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Polypus of Small Intestine associated with Intussusception.—Fibroma of Cerebral Dura Mater depressing Rolandic Region without Symptoms.—Hæmatoma Auris.—Mitral and Tricuspid Stenosis—Aneurysm of Internal Carotid Artery.—General Arteritis.—Primary Malignant Growth of Corpora Cavernosa.—Par-epididymal Cyst—Malformation of Heart.—Pregnancy in Bicornate Uterus.

AN ordinary meeting of this Society was held on May 3rd, the President, Sir George Humphry, in the chair.

Mr. LOCKWOOD showed a Polypus of the Small Intestine which was associated with Intussusception. The polypus was globular, and had a diameter of about three-quarters of an inch. It was fastened to the wall of the ileum by a short neck. Its point of attachment was about two and a half feet from the cæcum. It was of a firm consistence, and covered with mucous membrane, with its interior composed of fibrous and muscular tissue, and with a calcareous nodule in the centre. Below the polypus was an intussusception about five inches long. The mesentery having been dragged into the bowel with the intussuscepted gut, the tumour was held against the posterior abdominal wall. As these conditions caused intestinal obstruction, laparotomy was done; but all attempts at reduction were unavailing, and therefore the intussusception was excised. Owing to collapse, the ends of the ileum were not united, but brought out of the wound by Mr. Thomas Smith. The polypus was discovered during this operation, and removed. It seemed clear that the polypus was of long standing. The patient was a woman aged thirty, and the calcareous nodule suggested that she had had it many years—perhaps all her life. Its occurrence at or near the position of the vitelline duct also suggested that it had a congenital origin. The relation of the polypus to the intussusception was also a point for discussion. Usually the polypus was pendant from the lower end of the intussusceptum, but here it lay above. Probably the sequence of events had been that the polypus had caused an obstruction, and the intussusception had been formed during violent peristalsis and by the lower gut invaginating over the upper.—The PRESIDENT remarked that he presumed the calcification indicated degeneration of some previously existing active tissue.—Dr. CHARLEWOOD TURNER said there was a specimen similar to that shown in the London Hospital museum, in which the polypus was at the top of the intussusception, and probably stopped the latter from increasing.—Mr. SHATTOCK observed that calcification of fibromata was rare, while that of myomata was common, and he suggested that the tumour in the present case was of muscular nature.—Dr. HALE WHITE referred to a specimen he had shown some time ago of polypus attached to the upper part of the jejunum. There was no calcification, but it was associated with intussusception.—Mr. STEPHEN PAGET asked whether growths commonly occurred at this point or new formations other than Meckel's diverticulum.—Mr. LOCKWOOD, in reply, thought it was the tightness of the mesentery which stopped the progress of the intussusception. As to the histology of the polypus, it had been macerated in the gut for some time, which obscured the details of its structure, but it was certainly not a pure myoma. No other pathological condition was present. Constrictions were sometimes met with in this position, though he admitted that the explanation of these narrowings would not equally account for polypus.

Mr. EDGAR WILLETT showed a specimen of a Fibroma, measuring nearly two inches in diameter, which arose from the dura mater, and had caused a corresponding depression in the cortex over the upper part of the fissure of Rolando. The interest lay in the fact that no symptoms whatever existed during life, the patient being a healthy woman, who died from acute double pneumonia. Microscopical sections of the tumour were also shown.—The PRESIDENT remarked on the extreme pressure the brain had undergone without producing symptoms.

Dr. E. T. WYNNE brought forward several specimens of Hæmatoma Auris. Having referred to the described pathological accounts of this lesion by Tishkoff and others, he exhibited a series of horizontal sections through the ear, which demonstrated not only the amount of the deformity, but the situation of the blood-clot. His specimens showed that degenerative changes took place in patches in the cartilages; then vascular processes developed from the perichondrium, and, passing inwards, entered and broke up the cartilage into segments; blood was also extravasated in the subcutaneous tissues. The deformity of the ear was caused by the fracture of the cartilage in this manner and the fixation by blood-clot of the displaced fragments. The specimens were taken from patients who were chiefly general paralytics from thirty to fifty years of age.

Dr. ARNOLD CHAPLIN showed two specimens of Stenosed Mitral and Tricuspid Cardiac Orifices. The first was taken from a girl aged eighteen, who was admitted with shortness of breath, swelling of the legs, and subnormal temperature. There was also ascites, with a greatly enlarged liver. At the cardiac apex there was a presystolic bruit, followed by a faint systolic murmur; the lungs were much congested, and there was an attack of hæmoptysis two days before death. There was no history of acute rheumatism or of chorea, but an attack of scarlet fever occurred two years ago. The shortness of breath had existed for the last three years. At the necropsy there was found stenosis of both mitral and tricuspid valves, and there were recent infarcts in the bases of the lungs. He thought the tricuspid disease was due to congenital causes, and that it had given no trouble until the mitral stenosis developed later, the latter being due to a rheumatic attack associated with scarlatina. The second specimen was removed from a patient aged twenty-five, who had suffered from rheumatic fever when fourteen years of age, and since then had had shortness of breath, swelling of the legs, œdema, and cyanosis. The heart was enlarged, there being hypertrophy of all the chambers, the mitral valve being much stenosed and the tricuspid little so. He thought that in this case the narrowing of the tricuspid orifice was the result of chronic inflammation due to strain thrown on the right heart.—Dr. ROLLESTON said that in nearly all the collected cases there was stenosis of both sides, and if this were so, the lesion was presumably not congenital, for congenital disease usually attacked the right side alone. He held that the tricuspid lesion was secondary to the mitral, and due in all cases to chronic inflammation produced by strain. If the case had lasted a long time stenosis was more likely to occur than regurgitation.

Dr. WALTER EDMUNDS showed an Aneurysm of the Internal Carotid Artery, with syphilitic occlusion of the left subclavian and narrowing of other arteries. The patient, a male, aged thirty-six, was admitted to St. Thomas's Hospital, under the care of Sir W. Mac Cormac, on Nov. 6th, 1891, suffering from a pulsating tumour in the neck. It had been noticed a month, and had been rapidly increasing in size; it caused no pain or discomfort, but was somewhat tender to the touch. A few days before admission he had had a sudden attack of giddiness which caused him to fall, but he soon recovered. The tumour was on the right side of the neck, and situated near the bifurcation of the carotid; it pulsated forcibly and expanded with pulsation. Examination of the tumour sometimes caused an attack of faintness. There was no pulsation in either temporal artery, nor could any pulsation be detected in any part of either arm; a loud murmur could be heard about the base of the heart. There was a history of a venereal affection twelve years previously, and of cutaneous ulcers and of hair falling out two years ago. No operation was undertaken, the patient being very ill. He died comatose Nov. 18th, 1891. At the necropsy the heart was somewhat enlarged, pericardium adherent, but adhesions could be readily broken down; a rounded prominence, two inches in diameter, projected from the groove between the right auricular appendage and the pulmonary artery. On section this proved to be a gumma which was breaking down in its centre. The arch of the aorta was uniformly thickened, the thickening being mainly of the outer coat; the thickening extended to the innominate. The second part of the right subclavian was greatly thickened in its outer wall, and the lumen was so reduced as only to admit the passage of a bullet probe; the right axillary, brachial, and radial arteries were small and thin-walled, but showed no sign of disease. The right common carotid was nearly normal. The right internal carotid had springing from it, close to its origin, a globular aneurysm two inches and a half in diameter. After the origin of the aneurysm the internal carotid continued normally. The external carotid was narrowed and adherent to the aneurysm.

Digitized by Google

The left common carotid was greatly narrowed at its origin from the aorta, and would only just admit the passage of a bullet probe; the left external and internal carotids were also narrowed. The left subclavian was narrowed at its origin, and at the distance of three-quarters of an inch from the aorta it became completely impervious, ending in a fibrous cord. The descending aorta was enormously thickened, the thickening being mainly in the outer coat. The abdominal aorta and iliac arteries and also the intracranial arteries were normal. The liver, kidneys, and spleen were all enlarged, but showed no sign of past syphilitic disease.

Dr. HERBERT HAWKINS showed the Aorta of a child aged eleven, who died in St. Thomas's Hospital, as it was supposed, from acute nephritis. It was found at the post-mortem examination that there was disease of the aorta from end to end; of the common carotid, subclavian, and internal carotid arteries of both sides. The renal arteries were thrombosed. The disease consisted of grey translucent patches, which showed microscopically a development of uniform cellular tissue between the elastic lamina and the epithelium, and some of the patches showed a deposition of firm white clot upon the endothelium. The spleen showed signs of old disease. For three inches above the bifurcation of the aorta there was a lamina of firm clot nearly closing the lumen. There was also similar disease throughout the pulmonary arterial system. There was no definite history of congenital syphilis, but two other children had died in infancy, and he thought the case was probably of syphilitic nature.

Mr. HURRY FENWICK showed a specimen of Acute Traumatic Epithelioma of the Root of the Penis. The patient, aged forty-seven, began to suffer from priapism three days after the receipt of a blow in the crutch. Hæmaturia appeared at once, and continued until near the termination of the case. The penis became erect, increased rapidly in girth, and finally sloughed away. The duration of the case was three months. Secondary deposits were found in the right kidney, liver, and lung, the initial deposit being apparent in the region of the bulb.—Dr. RATCLIFFE asked if calculi were found in the carcinomatous kidney, for stone had more than once been found in connexion with squamous epithelioma of that organ.—Mr. SHATTOCK was able to confirm this observation, and added that a large sarcoma of the crus penis was recently removed in St. Thomas's Hospital.—Mr. FENWICK, in reply, said that no calculi were present, and he had only found stone in one case out of eight of malignant disease of the kidney under his observation.

Mr. SHATTOCK showed a Testicle between which and the vas deferens and, in close relation with the epididymis, was a cyst, which from its relations, had clearly arisen in a vas aberrans. He named it "Parepididymal," since, like the organ of Giraldès, such vasa aberrantia were remnants of Wolffian tubuli related to the epididymis. That the cyst shown had no connexion with the Müllerian duct appeared from the fact that the hydatid of Morgagni between the head of the epididymis and body of the testicle was present. In a case of persistent Müllerian duct lately reported by Mr. Lockwood, the duct, as in Dr. Ord's well-known case, descended from the kidney towards the prostate; and on the corresponding side the hydatid of Morgagni was absent. Why, in both these instances, the upper end of the persistent duct remained connected with the kidney and did not migrate with the testicle into the scrotum had not, so far as the author knew, been satisfactorily explained.—Mr. DAVIES COLLEY inquired as to the contents of the cyst, which appeared to him clinically to resemble a spermatocele or an encysted hydrocele.—Mr. SHATTOCK replied that the contents were not examined, but that they were probably of the same nature as those of an ordinary encysted hydrocele.

Mr. W. W. H. TATE showed a specimen of Malformation of the Heart taken from a man aged twenty-three, who was admitted into University College Hospital, under Dr. Vivian Poore, with pneumonia. There were loud systolic and diastolic murmurs heard over the mid-sternal region. There was no cyanosis and no history of previous cardiac disease. The patient died of pneumonia five days after admission, and at the necropsy a communication between the aorta and right ventricle was discovered, there being a passage from the aorta at the lower part of the sinus of Valsalva and ending in a perforation in a trumpet-shaped membrane situated between the septal and infundibular segments of the tricuspid valve. He believed that the case was unique, and that it arose from a hernial protrusion of the aorta into the right ventricle, which afterwards perforated.—Dr. HALE WHITE said that a boy three years of age, who had had influenza, came under his notice at Guy's Hospital with a loud to-and-fro murmur over the whole of the chest. At the post-mortem examination there was found an aperture in the undefended space at its upper part, and there was a funnel-shaped projection, like that in the specimen shown, which passed into the right ventricle. He regarded the case as one of congenitally imperfect septum in which the aorta had bulged into the right ventricle and had then given way. A systolic murmur was present whenever the left ventricle communicated with the right, and to this a diastolic murmur was added if the aorta also opened into the right ventricle.

Dr. J. R. RATCLIFFE of Birmingham showed a Uterus Bicornis, the left horn of which was pregnant. The patient was a woman aged thirty, who was brought into the General Hospital at Birmingham after a crane accident, and she died of fractured pelvis. The uterus showed two horns of nearly equal size, both measuring four inches and a half in length and six inches in circumference. In the left horn was a fœtus of between the second and third month of gestation; the placenta was attached to the posterior surface of the cavity. The vagina was five inches long and very broad, with a ridge on its anterior and posterior walls. The right ovary contained a well-marked true corpus luteum. The woman had had one normal labour and no abortions. She was not aware that she was pregnant, for she had menstruated regularly. This latter fact made the case of great interest on account of the possibility of superfœtation, and the specimen also raised the question of the manner of transference of the ovum from the right ovary to the left horn.

The following card specimens were shown:—

Dr. E. T. WYNNE: Sarcoma of Gall-bladder and Genital Organs.

Dr. H. D ROLLESTON: Guinea-worm in Subcutaneous the Tissue of Calf twenty eight years.

Mr. ALBAN DORAN: Adeno sarcoma of Breast weighing 8lb.

Mr. W. F. HASLAM: Sebaceous Horn.

Mr. S G. SHATTOCK: Columnar-celled Carcinoma of Male Breast.

Mr. J. H. TARGETT: (1) Congenital Myxoma of Neck; and (2) Ulceration of the Intestine after Fracture of the Spine.

HUNTERIAN SOCIETY.

Hydatid of Spleen.—Graves' Disease.—Eye Diseases.

A MEETING was held on April 27th, F. Gordon Brown, M.R.C.S., in the chair.

Dr. JAS. GALLOWAY read for Mr. HOPE GRANT and Dr. E. A. SNELL notes of a case of Hydatid Disease of the Spleen, with the discharge of membranes from the rectum twelve years later. The patient, a female, when aged eighteen years suffered from a large tumour in the left side of the abdomen, having a notch in front. Two years later a copious watery discharge, filling two chamber utensils, came away with the urine, and the tumour nearly disappeared. Ten years later, having in the interval enjoyed good health and borne five children, she passed, after much forcing pain, a mass of membranes per rectum, and she continued to pass pus both by rectum and urethra. There was still a small tender swelling in the splenic region. The membranes were shown. Dr. Galloway had examined them, and found very characteristic hydatid structure.

Mr. CARDEW read a paper on the Electrical Treatment of Graves' Disease. He recommended the use of the continuous current from two to three milliampères in strength; the positive electrode, three inches in diameter, to be placed on the nape of the neck opposite the seventh cervical spine; the negative electrode, one inch and a half in diameter, to be moved up and down the side of the neck, along the anterior border of the sterno-mastoid. The electrodes to be well soaked in hot water and applications to last about six minutes, three times daily. The immediate effect, as demonstrated by sphygmograms taken immediately before and after an application, was a diminution of the suddenness, violence, and rate of the heart beat, with less feeling of tension in the eyes when exophthalmos was present. A

Digitized by Google

stronger continuous current was found to cause, as evidenced by sphygmograms, an increase of the cardio-vascular excitement. A strong faradaic current had a like effect; whilst a weak faradaic current produced no effect; with a moderate current either no effect or the same as with the continuous current was produced. This latter method was therefore adopted as the most effective, and also because it was self-applicable. He found that if prolonged the application caused an increase of excitement; he therefore never used it for more than six minutes at a time. At least three applications a day were needed, since the effects lasted but for a few hours. A small portable battery, having an electromotive force of about six volts, and a water voltameter to test the battery, were all that were required. It was difficult to order the treatment, so to speak, by rule of thumb, owing to the great variation in the resistance of the human body; but for all practical purposes this might be estimated at from 2000 to 3000 ohms, so that a battery having an electro-motive force of about six volts would be sufficient to produce a current of from two to three milliampères. The patient must be encouraged to persevere with the treatment and not be discouraged by temporary relapses.—Dr. HINGSTON FOX said that the erratic course of Graves' disease made one cautious in receiving therapeutical results. There were two leading means of general treatment: moral and hygienic control for the over-sensitive, excitable nervous system; and, secondly, nutritional helps. As to special means, belladonna had seemed useful in slighter cases; iodide of potassium, with bromides (and sometimes iron), in others. Leiter's cold coil to the thyroid was worth further trial. But nothing cured in the bad cases. He had used the weak constant current in about six cases, from a half to two milliampères. The patients liked it, and were willing to continue it long, and on the whole the results were encouraging. A cheap battery for out-patients' use was a desideratum.—Mr. MARK HOVELL approved of the electrical treatment.—Mr. E. A. BURGESS had used in India the inunction of red iodide of mercury ointment over the thyroid with exposure to the sun, and had found much benefit.—Dr. F. J. SMITH asked how the electricity acted. Did it increase nervous energy, or did it increase the power of the nervous system to restrain the energy when formed? The general measures detailed by Dr. Fox could not be applied to indigent persons, and here electricity seemed to step in as a substitute.—Mr. W. LANG alluded to Dr. W. Fitzgerald's masterly paper on the disease in a Dublin journal, where experiments on rabbits were described, showing that disorder in the central nervous system close to the medulla was the acting cause. His own experience was limited to cases in which exophthalmos was complained of; he found potassium iodide and iron useful.—Dr. ARTHUR DAVIES asked as to the average duration of the electrical treatment, and at which stage Mr. Cardew began it. A case he had brought before the Society had recovered without special treatment; in another case the symptoms were of twenty-two years' standing.—Mr. CARDEW, in reply, said the moral and hygienic measures were of course needed. Cases might be divided under three categories: those which recover unaided, those which recover with drugs or electricity, and those which do not recover. Many of his cases were of long standing, and had been under good physicians. The dry battery he used cost £1; it could be made for about nine shillings. He could not tell how the electricity acted, or through what nervous structures. He had not had a case under treatment for longer than ten months, and he treated them at all stages.

Mr. W. LANG read a paper on the Treatment of certain external Eye Affections—chiefly epiphora, follicular conjunctivitis, phlyctenular ophthalmia, and corneal ulcers and opacities.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

Influenza.

A MEETING of this Society was held on April 1st, Mr. H. W. Roberts, President, in the chair.

Dr. PITT opened the discussion on this subject by reading a short paper on the history and etiology of the disease. He referred briefly to the epidemics of 1693, 1733, 1762, and 1833, and described in detail the manner in which the recent epidemics—viz., that of Christmas, 1889; February, 1891; and November, 1891—first appeared, and how they spread. The disease is undoubtedly contagious, and there is a contagium vivum, but bacteriologists are not quite certain yet that it has been identified. The incubatory period is about two days. The contagium is capable of multiplying in the atmosphere, the infectiousness being enormously increased at crowded meetings of men, where ventilation is defective. It has been suggested that the air currents which descend to the earth in anti-cyclonic areas may be the means of the convection of disease simultaneously to places situated some degrees apart. On many occasions the epidemics have been known to occur among horses a short time before men were attacked. Unstable weather, fogs, and unusual swarms of insect life have frequently preceded attacks.

Dr. PRIOR PURVIS gave a short account of the epidemic of 1837, as it occurred in Greenwich in cases under his own observation. The mortality was very excessive in those advanced in life, one of the most striking symptoms being the rapidity with which patients became asphyxiated by the blocking up of the bronchial tubes, with a very tenacious mucus like bird-lime. The treatment at first adopted was "antiphlogistic," and the patients were bled, but, as this proved fatal, it was given up, and salines and ammonia were exhibited.

Mr. LOCKHART said that he remembered the 1837 epidemic when it occurred in Liverpool. The treatment there with ammonia and salines was very efficacious.

Mr. MOORE drew attention to the fact that Pfeiffer and others claimed that they had discovered the influenza bacillus.

Sir WILLIAM MOORE then read his paper on the Comparison of Influenza with Dengue. He said that the symptoms of dengue were chiefly at first headache, restlessness, chilliness, debility, pains in the back, limbs, eyeballs, and joints—febrile excitement. Sometimes the pains in the joints and fever commence suddenly, there being no preceding feelings of malaise. In from twelve to twenty-four hours an eruption appears like scarlatina; the glands of the neck, groin, or axilla may become tender; the joints swell; there is generally sore-throat, and the testicles may swell. During the eruption the temperature rises to 103° or 105°. This rise only lasts one or two days, disappearing as the rash disappears, after which there is almost total remission for three or four days. Then, with an accession of fever, a second eruption resembling measles appeared. A third attack may occur. Albuminuria may be a sequel, but gradually disappears. Dengue, therefore, more resembles scarlet fever than influenza, but differs from it in its being more decidedly epidemic, high temperature more rapidly attained and dissipated, the severe muscular and joint pains very characteristic of dengue but not scarlet fever, and in the fact that dengue does not confer protection against recurrence. Dengue is regarded as infectious, but the following experience appears to prove that it is non-infectious. In the autumn of 1874, when dengue was prevalent in all the villages of the country, the camp of the chief Political Officer of the Native States of Rajpootana, some 1500 strong, marched about 300 miles, from Aboo to Agra, at the rate of ten or fifteen miles daily, encamping as usual near the different towns, and no measures to prevent communication were or could be enforced. As Superintendent-General of Dispensaries in Rajpootana, Sir W. Moore was passing daily from the camp to the villages, and he constantly saw persons suffering from dengue; but not a single case occurred amongst the camp people, although there were the usual number of agues and ordinary maladies at the camp hospital. Possibly the tent life, with fresh air and ventilation, rendered the poison of dengue innocuous.

Mr. THOMAS MOORE followed with a paper on Differential Diagnosis. He mentioned the sudden invasion, malaise, depression, rapid rise of temperature, slow pulse, tongue moist and furred with red edges, and the thick, tenacious expectoration. He said the diseases it was most difficult to diagnose from were rheumatism, ordinary catarrh, and neuralgia. In rheumatism the characteristic rheumatic tongue and acid perspiration helped the diagnosis. Again, when pneumonia was present, was it a sequel of the influenza or quite unconnected with the epidemic? He thought that the pneumonia of influenza was very rarely lobar pneumonia, and the sputum was less rusty coloured. The very great prostration afterwards was the most characteristic symptom and helped the diagnosis "after the event."

Dr. FRANCIS TAYLOR then read his paper on Complications. The troubles referred to the respiratory tract claim the first place, and of them bronchitis is at the head. The

Digitized by Google

smaller tubes were specially liable to be implicated, and the bronchitis of influenza was very often of a marked suffocative type. With regard to pneumonia, although ordinary cases of croupous pneumonia were rather common at the time of the epidemic, as a complication of influenza he had only seen one doubtful case. Phthisis, pleurisy, empyema, sore-throat, and tonsillitis were met with as complications. Non-suppurative and suppurative otitis media have been fairly common. With regard to heart complications, in pericarditis secondary to pleurisy, with weakness of the heart muscles, he had not noticed the slow pulse during the febrile stage, but at the end of that period had seen it fall to 50 or less. Angina pectoris and pseudo-angina were met with. Nervous system: Had seen a case of meningitis. Various forms of neuralgia were very common, some of them being due to local neuritis; jaundice, prostatitis, cystitis, and suppurative parotitis were mentioned as complications. Finally, he remarked on the prolonged convalescence, which was generally longer in those who used their brain, and was often accompanied by mental depression.

The President, Messrs. Lockhart, Moore, Hartt, Cable, Marshall, and MacGavin, and Drs. Prior Purvis, Horrocks, Pitts, Tayler, Moore, Wainewright, Peachey, and Ernest Clarke took part in the discussion which followed the various papers.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Exhibition of Cases.

A MEETING of this Society was held on April 8th, Dr. D. Lloyd Roberts, President, in the chair.

Dr. WALTER, of Manchester, showed a patient who had for many years suffered from a growth of the vulva, and asked the opinion of the members as to its nature.

Dr. LAUDER, of Manchester, showed two patients who lately had each a large fibroid tumour of the uterus removed at the Manchester Southern Hospital, and exhibited the specimens. The operation might be briefly described as an amputation of a myoma of the uterus by means of anterior and posterior flaps, consisting of peritoneum. After the tumour had been lifted out of the abdominal wound, the large vessels entering it from the broad ligament on either side were ligatured close to the growth with strong silk, and then divided. Running from the two lateral wounds thus made anterior and posterior incisions through the peritoneal covering of the tumour were carried, at a distance calculated to ensure flaps sufficient to cover in the stump. These incisions were made gradually, each portion of peritoneum being ligatured separately before being cut. The peritoneum was at the same time peeled downwards, and its raw surfaces united by means of silkworm gut sutures. After thus enucleating the tumour any large vessels, from which hæmorrhage might be feared, were tied separately with catgut. The flaps of peritoneum were then more accurately adjusted, and during this process any hæmorrhage which might occur was easily controlled by including the bleeding vessel in one of the sutures. Finally, the stump was dropped, a glass drainage-tube inserted behind it, the peritoneal cavity flushed, and the abdominal wound closed in the usual way.—Dr. WALLACE, of Liverpool, said that he had done this operation years ago, but had of late given it up, as it had one drawback—viz., the uterine cavity was liable to be opened. Still, he thought that he might again have recourse to it.

Dr. WALLACE, of Liverpool, showed a specimen of Tubal Gestation, which had been removed by operation. It was probably unique, as the fœtus was partly extruded from the fimbriated extremity of the tube, so that its development had taken place between this end of the tube and the ovary.

Mr. WRIGHT, of Leeds, related a case in which an unfortunate accident occurred during abdominal section. During the removal of a double dermoid ovarian cyst a pair of torsion forceps was placed upon a large adhesion, in the neighbourhood of the liver. On account of faintness the operation had to be hurriedly brought to a termination. The patient made a good recovery, but subsequently complained of tenderness in the epigastrium. Later on, a nodule was found to have formed at the upper part of the cicatrix. This was, seven months after the operation, cut down upon, when the pair of torsion forceps was found, and removed with difficulty. A fæcal fistula afterwards formed, but ultimately closed, and the patient did well.

Dr. HELLIER, of Leeds, exhibited drawings (1) of an apoplectic placenta; (2) of an impacted Zwanck's pessary.

Dr. MARTIN, of Sheffield, read the notes of a case of puerperal eclampsia.

Mr. R. FAVELL, of Sheffield, described a case of abdominal section for a small impacted ovarian tumour (specimen shown), where death was caused by omental adhesions.

Dr. DONALD, of Manchester, read a paper on the treatment of placenta prævia.

Reviews and Notices of Books.

Outlines of Theoretical Chemistry. By LOTHAR MEYER. Translated by P. PHILLIPS BEDSON, D.Sc. Lond., B.Sc. Vict., F.C.S.; and W. CARLETON WILLIAMS, B.Sc., F.C.S. London: Longmans, Green, and Co. 1892.

A CAREFUL and intelligent reader should gain a very clear conception of the modern views of theoretical chemistry from a perusal of this comparatively small but none the less classical work. Lothar Meyer is one of the best living authorities on the subject of chemical theory, and no apology need be offered by the co-elaborator of the great law of the periodicity of the elements for issuing a text-book under the above title, although similar works have already been published by Polis, Remsen, and Ostwald. The volume contains practically a *résumé* of the arguments advanced in the same author's larger work on the "Modern Theories of Chemistry." Professor Bedson, of the Durham College of Science, and Professor W. Carleton Williams, of the Firth College, Sheffield, are the translators of both volumes, and they have done their task well. The old but ever-fascinating story of the development of the theories of chemical science is gradually told that not merely students, but the "friends of scientific investigation who have neither the intention nor the time to concern themselves with the details of chemical investigation, may become acquainted with the general conclusions deduced." Thus, the definition and the scope of chemistry are first discussed; then follow, in natural order, short but fully instructive sections on methods of investigation, the quantitative composition of compounds, the law of multiple proportions, the atomic hypothesis, Dalton's views, isomorphism, specific heat, the kinetic theory, molecular weight, classification of the elements, the periodic system (in which section, by the way, Newland's work is distinctly recognised), until at last the reader is brought to study the more recent bases of argument. Round numbers as representing the atomic weights of certain elements are rigidly avoided, as indeed they should be in a work devoted to the discussion of theory. The weight of the atom of oxygen, for instance, is regarded as 15·96, not 16; and silver, 107·66, not 108; carbon, 11·97, not 12; and sulphur, 31·98, not 32. In the section on the molecular weights of gases it is shown how the kinetic theory of gases has afforded a means of estimating approximately the weight of a single molecule. Thus a particle or molecule of hydrogen, the lightest of all gases, has been calculated to weigh ·000,000,000,000,000,000,000,004 gramme (or, as it is obviously misprinted, grammes). In other words, one quadrillion molecules of hydrogen weigh about 4 grammes. Similarly a cubic centimetre of hydrogen measured at 20° C., and under a pressure of 760 millimetres of mercury, contains so many molecules that if they were laid side by side they would cover 9500 square centimetres, or very nearly a square metre. Accordingly, for each twenty trillion particles but a very small surface would be required to accommodate them, for in the length of a millimetre from four to five million particles could be arranged in a series! Of

Digitized by Google

course these numbers cannot lay claim to any special accuracy, still they serve to give some idea of the minuteness of molecules and of atoms also. One important kind of phenomenon appears to have been overlooked—namely, that while certain sections are devoted to optical isomerism and to a dissertation on asymmetrically linked carbon atoms, there is no mention made of the molecular magnetic refraction of bodies: the subject which Perkin so ably investigated. He showed that although under normal conditions an organic substance cannot affect a ray of polarised light unless its molecule contains an asymmetric atom of carbon, yet when surrounded by a coil of wire conveying electricity, or placed between the poles of a powerful magnet, any substance will become active. Proceeding on these lines he has obtained some very valuable results, which have materially added to our knowledge of the constitution of organic compounds.

English chemical literature has during the last year or so been considerably enriched by the additions of translations of standard German works. The large works of Beilstein, Wagner, and Lothar Meyer are cases in point; and now to these must be added the work before us, for it is a volume which should grace the shelf of all scientific libraries, whether private or public.

Outlines of Zoology. By J. ARTHUR THOMSON, Lecturer on Zoology in the School of Medicine, Edinburgh. With thirty-two full-page Illustrations. Edinburgh and London: Young J. Pentland. 1892.

IN a short preface Mr. Thomson states that this work is intended to serve as a manual which students of zoology may use in the lecture-room, museum, and laboratory; and as an accompaniment to several well-known works, we consider it fulfils its intended purpose well, and those who wish to make themselves acquainted with the progress that has been made in this subject may with advantage compare the sections of the present volume with those of Rymer Jones's "General Outline," published in 1871, or of Carpenter's "Zoology."

The volume may be divided into three parts: the first embraces general physiology, morphology, reproduction and life history, palæontology, geographical distribution, and evolution of animals; the second part deals with the characters and classification of the invertebrata, and the third with those of the vertebrata. Nearly the whole of the first part is the product of the researches that have been made during the last half of the present century, and, though lightly dealt with here, are yet sufficiently discussed to render the work a useful companion to any systematic course of lectures. In the chapter on Echinodermata Mr. Thomson discards the "fin-worm" theory of Haeckel, and agrees with the embryologists that the holothurians are, in form at least, nearest to the worm-like ancestor, whilst the interpretation which regards the five-armed starfish as a decentralisation of a flattened sea urchin is, he thinks, more plausible than that which regards the sea urchin as the concentration of a puffed-up starfish. A plate with description is devoted to the typical structure of each of the divisions of the echinoderms, and drawings are given of the several larval forms of auricularia: pluteus and bipinnaria. This arrangement is carried out in all the sections, and Mr. Thomson does not hesitate to introduce a few remarks in regard to the geological relations of the various orders or genera when these are of interest. Thus he points out that the race of scorpions is of very ancient origin, one having been found in Silurian strata, and others nearly resembling those now alive in the carboniferous formations. In like manner he enlivens his pages with comments on the natural and life-history of the animals he describes. Thus, in speaking of spiders, he remarks that the males are much smaller than the females. It has been calculated that the disproportion is sometimes such as would be observed if a man six feet in height and weighing about 11 st. were to wed a giantess about eighty feet high and weighing 200,000 lb. He believes that the smallness of the males is in great part due to the fact that they are males, though some explain it by saying that the smaller the males are the less likely are they to be caught by their frequently ferocious mates. He acknowledges that it is difficult to understand how this characteristic smallness, though perhaps advantageous and likely to be favoured by natural selection, could be entailed on the male offspring only. In evidence of the careful manner in which the author has done his work, we may remark that Dr. E. C. Sterling's new type of marsupial notoryctes typhlopod is given, and the chief points in its structure are described.

We recommend the book very strongly as a full and reliable guide to the zoological student. The plates, though rough and diagrammatic, are clear and accurate. The paper, print, and general get-up of the book are excellent, and reflect credit on the publisher.

A Practical Treatise on Fractures and Dislocations. By FRANK HASTINGS HAMILTON, A.B., A.M., M.D., LL.D., late Professor of Surgery in Bellevue Hospital Medical College &c. Eighth Edition, Revised and Edited by STEPHEN SMITH, A.M., M.D., Professor of Clinical Surgery in the University of the City of New York, and Surgeon to Bellevue and St. Vincent's Hospitals, New York. Illustrated with 507 Woodcuts. London: Smith, Elder, and Co. 1891.

DR. HAMILTON'S work on Fractures and Dislocations has for so many years held the first place among modern treatises on this important branch of surgery that we are glad to see that its publication is not to cease with the life of its distinguished author. No better choice of an editor could have been made. Dr. Stephen Smith was closely associated for many years with Dr. Hamilton as his pupil, colleague, and friend; he knew the great aims Dr. Hamilton had in writing the book originally, and in preparing its successive editions, and the devoted labour he for years lavished on this work. In preparing this edition for the press, Dr. Smith has maintained the high character of the work most fully, and has not departed from Dr. Hamilton's lines except in small details. Some methods of treatment which are quite out of date now have been omitted, and modern plans of treatment, such as the operative treatment of fracture of the spine, are judiciously referred to. The most recent works on the subject have been consulted and drawn upon, many quotations from Mr. Pick's monograph, for instance, being intercalated. The number of the illustrations has been greatly increased—by over 100—but these additions, while very welcome and a great improvement to the book, are not novel, most of them being taken from Erichsen's, Bryant's, Stimson's, Pick's, and Pye's well-known works. The editor, in spite of these additions, has succeeded in reducing the bulk of the book by no less than 160 pages. This has been done by placing the clinical records of cases, extracts from other writers, and tabular matter, in a smaller type. On the whole, this edition is the best that has yet been published, and does equal credit to the memory of the author and the tact and ability of the editor.

The Rational Cure of Deafness and Discharge from the Ear. By Drs. SEXTON and DUANE. New York: J. H. Vail and Co. 1891.

IN this little work the authors bring forward their operations of removal of the tympanic membrane and ossicles in cases of chronic deafness with tinnitus and

Digitized by Google

in obstinate perforative otorrhœa. They do well to point out forcibly that the indications for the performance of these operations must be very carefully studied before they are undertaken. They also lay stress upon the difficulty of their execution, and it is obvious that they should not be attempted by anyone who has not large experience in the ordinary manipulations of aural surgery. Details of the operations and requisite instruments are not given. The reader is referred for these to Dr. Sexton's work on Diseases of the Ear. Eleven cases of the operation for chronic catarrh and nine for suppurative disease are quoted. These are but few out of many similar ones, and are not to be looked upon "as mere isolated instances of lucky cures." The results of the cases related are certainly remarkable, and we naturally ask, Have no failures resulted in the large experience of the operators? Have no serious results ever occurred? The very completeness and universal success which the authors seem to claim for these operations raise a legitimate feeling of doubt in the minds of those accustomed to follow and accurately note the results of even the simplest operations of surgery.

In cases of chronic catarrh, with adhesions and tinnitus, we can easily see how inflammatory affections of the secondary membranes or subsequent cicatricial formations, would cause the operation to fail. In cases of chronic otorrhœa, should the operator feel assured that the malleus and incus are mere carious sequestra, he would do right to remove them. But all practical surgeons and pathologists know that in a considerable proportion of the worst cases caries exists in the walls of the tympanum, and especially in the mastoid, the pus finding its way to the tympanic cavity through long and complicated sinuses. In such cases, the operation here given could hardly succeed. Again, the treatment of otorrhœa by ordinary methods is by no means so generally unfavourable as the authors would have us believe. Many such patients, by systematically practising the ordinary principles of cleansing the ear, pass through a long life unscathed by suffering or serious disease. It is in the neglected cases that the fatal results of this affection so often come before us.

The authors are entitled to have full consideration shown to their views, and certainly they should not be opposed with the "savage bigotry" complained of in the preface. We fear, however, that they claim too much for these operations. Any surgeon who proposes to undertake them will remember the difficulty of their full performance, will long study the indications present in any particular case, and will especially bear in mind the responsibility of operating in a cavity in close proximity to the brain and its meninges, and among parts difficult to render aseptic, which have been sodden for years in fluids swarming with micro-organisms of the most dangerous nature.

OUR LIBRARY TABLE.

The Archives of Pediatrics. Edited by WILLIAM PERRY WATSON, A.M., M.D. Vol. IX. No. 97, January, 1892. New York: Fairchild and Company.—The January number of the *Archives of Pediatrics* is above the average. It opens with an interesting original communication, by Dr. Northrup of New York, on "Scorbutus in Infants; American Cases (illustrated)." The details of eleven cases are given. The writer has taken considerable pains to obtain reports of cases, and his monogram (in which full justice is done to Dr. Cheadle and Dr. Thomas Barlow) is the best contribution to the subject we have seen from the American continent. There are two other original treatises. One, by Dr. Howard, jun., on "A Case of Congenital Malformation of the Heart"; the other, by Dr. O'Dwyer, on "An Improved Method of Performing Artificial Forcible Respiration." This is a modification of a method of producing artificial respiration devised by Dr. Geo. E. Fell of Buffalo. His method consists in forcing air into the lungs by means of a foot bellows—the connexion between the bellows and the lungs being effected by means of rubber tubing attached to a cannula in the trachea or to a mask applied over the mouth and nose. Dr. O'Dwyer has improved on this plan by devising a set of tubes which establish direct communication between the bellows and the lungs through the natural passages. Professor Jacobi contributes a clinical lecture, in which, amongst other things, he strongly advises in spinal paralysis the use of strychnia subcutaneously in preference to its administration by the mouth. Dr. Jacobi has little regard for proprietary medicines. We are inclined to think the profession will agree with him when he says, "Whatever medicines you hear about from me are officinal." Several interesting clinical cases are given, and there is a good "current literature" on hygiene and therapeutics, medicine, and surgery in their bearing on diseases of children.

The Dietetic Value of Bread. By JAMES GOODFELLOW, F.R.M.S. London: Macmillan and Co. 1892.—While, of course, it is extremely desirable that so important an article of food as bread should be made with scrupulous care, we can hardly go so far as the author of this text-book, who thinks that the people of England have been in a particularly bad state of health owing to the unsatisfactory way bread has hitherto been made. Yet this is the aspect of things which he assumes to have existed, for in the first chapter he expresses the belief that bakers, guided by a sound knowledge of certain particulars (that is, regarding hygienic requirements and the food value of bread), will do more than all the theoretical food reformers in England to help the people back to perfect health. The volume contains, however, a clear and lucid account of all that pertains to the "staff of life," its value as an article of diet and its chemical composition; and it would appear to be the only work that deals exclusively with the dietetic value of bread, although we are aware of one excellent work which deals certainly with the chemistry of the subject, besides also with many details of technical importance. Mr. Goodfellow has divided his book into six sections, and these when enumerated will give some idea of the scope of the work. Section I. treats of food, diet, and digestion; Section II., of white bread; Section III., of whole-meal bread; Section IV., of special breads; Section V., of diseases of bread; Section VI., of the medicinal properties of bread. The sections are in turn subdivided into chapters. The author makes some very sensible remarks concerning the value and use of whole-meal bread, as well as on adulterations and impurities in ordinary bread. Having made, as he states, an exhaustive series of examinations, he is entitled to speak with some confidence and authority on the latter subjects. Of the samples of bread examined by him in London, 333 out of 341 were pure, and only three were adulterated with alum. In the provinces, of 194 samples examined, 189 were pure, and only two contained alum. The work contains a valuable collection of analyses, and it will doubtless prove useful as a book of reference to students and others interested in the technics of bread. We have noticed but one serious error throughout the pages, and that is to be found in the formula of urea on page 11. It is written $(NH_2)CO_2$, instead of $(NH_2)_2CO$.

Bibliographie der Klinischen Helminthologie. Von Medicinalrath Dr. J. CH. HUBER.—Part II. gives the references to various works on Cysticercus Cellulosæ Rudolphi. After dealing very briefly with the history, the author follows the course laid down in the first portion of the work, and gives first the general literature on cysticerci in general; then general works on helminthology, in which the cysticercus

Digitized by Google

is discussed; next the German dissertations and French works, statistics, the general pathology and pathological anatomy; then in chronological order is given a list of the descriptions of the cysticerci in the brain, in the spinal canal, in the subcutaneous connective tissue and muscles, in the heart, liver, &c.; and of the cysticercus occurring in the same individual along with the tænia form. The same remark applies to this portion that applied to the first. It should prove an exceedingly useful list of references to any one working at the subject.

Premiers Secours en Cas d'Accidents ou de Maladies à Invasion Subité. Par le Dr. A. LÉON. Bordeaux: G. Gounouilhou. 1892.—This small work of eighty-one pages is illustrated by several lithographs. It deals with first aid to be rendered in cases of sudden illness and accidents and injuries, such as are unhappily of frequent occurrence in all large towns, cities, and centres of industry. The nature of the information is indicated by its title, and we have only to remark that it sets forth methodically and practically what is to be done and to be left undone until further and more skilled aid can be procured. The application of antiseptic principles to cases of traumatism is briefly but clearly inculcated. The information is arranged in four chapters, with an appendix, together with an interesting notice of the objects, composition, and work done by the Bordeaux Ambulance Society since its formation.

New Invention.

AN IMPROVED EVACUATOR AND TUBES FOR STONE IN CHILDREN.

DR. O. K. NEWELL some time ago published in the *New York Medical Record* an article on the improvement of evacuators for litholapaxy, and the later developments of the operation, and described an evacuator and special construction of straight tubes for use in such cases as they were suited to, laying especial stress upon the value of the straight tubes in conditions approaching the normal in adults, but especially in children. He also called attention to the short or, as he called it, the surgical distance into the bladder when the passage is engaged by the calibre of a metallic instrument. This distance, varying anywhere from two inches and a half or more in children to six or eight inches in adults. He now sends us a description of his evacuator, which he has since improved, without making material alterations in the principle of its construction. The taper joints are so improved that the form of stopcock is readily and unfailingly operated with a single finger. The evacuator is constructed on the principle that all of the fragments are received at the upper part of the bulb, that they are shot rapidly towards the bottom, sink at once into the receiver, and do not return through the tube. This has been shown to be in every way true, for even fine dust and sand may be quickly trapped with this instrument. Its chief advantages over all others Dr. Newell considers to be the fact that it is the simplest effective evacuator yet devised, that it is without any trap or valve, the bulb with receiver being of itself a trap; it has the shortest evacuating canal thus far made possible. It is the lightest evacuator yet made. Its capacity is nine ounces and three quarters. The form of stopcock, as already stated, is readily movable with a single finger. The evacuator is non-corrodible, being made of rubber and glass. According to his experience he considers these tubes are perfect as far as their application for evacuation of fragments from a child's bladder is concerned, there being no enlargement of the prostate in these cases or other abnormal conditions. The tubes were at first made of aluminium, and their lightness was an advantage, but the difficulty of working this metal has decided him to abandon the use of such tubes for the nickel-plated brass or silver ones.

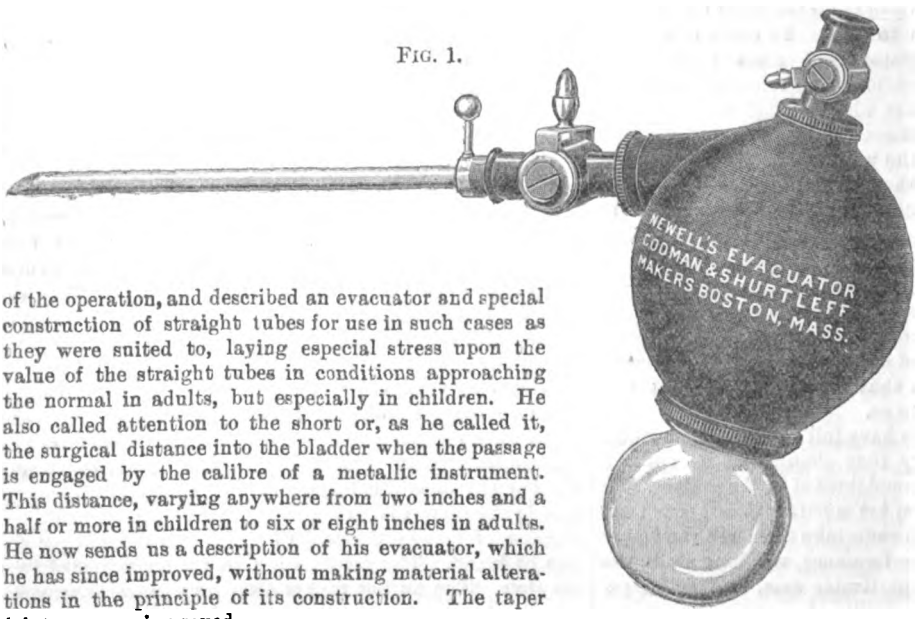

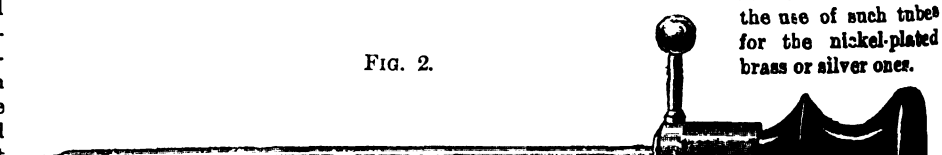

FIG. 2.

METROPOLITAN ASYLUMS BOARD.—At the usual meeting of the members of the Metropolitan Asylums Board, held on Saturday afternoon at the offices of the London County Council, Spring-gardens, the returns which were presented as to the fever and small-pox patients under the charge of the Board showed that, in regard to fever, 447 patients had been admitted during the fortnight, 45 had died, and 285 had been discharged recovered, leaving 1660 under treatment, or an increase of 117 as compared with the figures of the preceding fortnight. There were 54 small-pox patients in hospital, as compared with 45 in the preceding fortnight.

THE LADY AITCHISON HOSPITAL, LAHORE.—The annual meeting of this institution was held on Jan. 30th last, Lady Lyall presiding, in the unavoidable absence of Sir James Lyall. The report, which was read, was adopted. It was resolved to close the building and furnishing fund, paying the deficit of Rs. 30-4 1 from the current expenses fund. Some discussion took place as to the need of constructing a new City Dispensary; but, pending the receipt of funds for that purpose, a subcommittee was appointed to select a commodious house at a central part of Lahore city, and to report on the question of a new dispensary and its probable cost.

THE LANCET.

LONDON: SATURDAY, MAY 7, 1892.

DR. PYE-SMITH'S Lumleian Lectures on "Certain Points in the Etiology of Disease" range over wide ground and raise many points of extreme interest and importance. The subject is handled not only with wide knowledge but with true philosophic temper. The results arrived at are, as the lecturer says, mainly negative and destructive, but he adds, "we must get rid of superstitious remnants, misleading analogies, loose definition and illogical arguments before we can make progress in any branch of natural science. When the ground is cleared a solid structure may be built." Pathology is now undergoing the process to which so many other departments of science have had to submit—the process, namely, of overthrowing the false, in order to found the true, of uprooting the weeds in order to give the wholesome grain a chance of life. In the progress of science the human mind has always two tasks before it—first, the collection of facts; secondly, their generalisation and systematisation. We must first observe, then philosophise; but the process of accurate observation being slow and difficult, while that of specious philosophising is easy, there is a constant tendency for the latter process to outrun the former. Hence pathology, like so many other departments of science, is encumbered with doubtful theories, plausible but unverified hypotheses, question-begging epithets and the like. He does a good service who shows us how far and in what manner our theories have outstripped our facts, but the tendency to philosophise is an ineradicable instinct of human nature, which can never be wholly checked. "We must philosophise or die," said one of the most famous of Greek thinkers; and in all our impatience at the cumbrous and obstructive theories which have often impeded the true progress of medical science, we must never forget that a fact, while it remains isolated, is comparatively barren, and that it only becomes truly fruitful and light-giving when we generalise it, connect it with other facts, bring it under some higher law—in other words, until we philosophise.

Dr. PYE-SMITH at the outset announces the principle that "disease is as natural, as physiological, as health. No living thing is immortal, and life is a constant struggle against surrounding forces, in which each individual organism succumbs after a while, by handing on its life to its successor when it has ensured the victory of the race. Pathology is only a chapter in physiology, which for convenience we have separated from the rest." Whether disease is as natural as health depends, of course, upon our definition of "natural." We can understand how decay is as natural as growth, death as natural as birth; but we are not sure that enteric fever or pneumonia can in any true sense be said to be "natural." They are not part of the necessary evolution of the individual, although they have, of course, their place in the evolution of the race. This latter is evidently the point of view of Dr. PYE-SMITH, who says: "Let us look upon diseases, not as unnatural, lawless, heterogeneous, abnormal, revolutionary, but as parts of the vast order of creation. They are not to be explained by any single all-mastering principle of physical evil. The various ancient systems of pathology which pretended to discover a common origin of disease are all outworn, dead, or dying, as obsolete as the correlative systems of therapeutics which pretended to deal with disease as a whole by some universal antagonistic principle."

Dr. PYE SMITH enumerates the external agents which can injure or derange the ordinary functions of a living cell thus: (1) Mechanical injuries, (2) electrical changes, (3) extremes of heat and cold, (4) chemical agents. In addition to these the cell may be (*a*) starved for want of food; (*b*) stifled for want of oxygen; or (*c*) poisoned by its own excreta. Here we have the chief etiological factors in disease. As regards the much-disputed question of the influence of cold or chill in the causation of the more important diseases, the lecturer evidently doubts whether the local application of cold to any part is a frequent cause of inflammation of the subjacent organs. He questions whether "we find that bronchitis, pneumonia, or pleurisy follows the application of cold to the chest, and that enteritis or peritonitis is produced by cold to the abdomen, or nephritis by cold upon the loins." He points out that ice applied to the chest in cases of pneumonia, whatever its efficacy as a remedial agent, which he doubts, at least never produces inflammation of the lungs, and that ice applied to the head in meningitis or to the abdomen in intestinal hæmorrhage never causes inflammation of those organs. He thinks we are driven to the belief that "cold applied to the surface of the body has no local result beyond the effect upon the skin." The real mischief seems, he thinks, to depend upon "a sudden impression which we sometimes feel when exposed to a draught on going out of a hot room in winter, or on sitting, after profuse perspiration in summer. ..... The effect does not appear to depend upon the locality or the severity of the chill. In most persons in this country, and in temperate Europe and America, a coryza with sore-throat, followed by a slight catarrhal bronchitis, is by far the most common result; but in many persons, especially in the summer months, precisely the same kind of exposure of the face or head, which causes a common cold, will produce diarrhœa and other symptoms of catarrhal colitis, local pain, with irregular peristalsis and discharge of mucus, with furred tongue, loss of appetite, and slight rise of temperature; while in India, China, and the Southern States of America a precisely similar chill produces an attack of ague." It is evident that in putting these diverse results down to "chill" we are not doing much in the way of real explanation.

Dr. PYE SMITH draws attention to an important point, upon which we can entirely endorse his remarks—viz, that not only do acute diseases pass often into chronic, but that they are often developed out of chronic affections. Thus, phthisis often appears to begin acutely, whereas careful inquiry often brings out the fact that there has been antecedent failure of health, loss of flesh, &c. Abscess of the brain appears to begin as an acute disease, but it is found always to be preceded by injury, caries, or by primary suppuration. Even enteric fever often ensues upon weeks of

Digitized by Google

chronic diarrhœa. Genuine diphtheria is often preceded by non-specific and subacute angina.

Dr. PYE-SMITH strongly deprecates the frequent use of the term "diathesis." "To say that a man who has had rheumatic fever has a disposition to its recurrence is only to say that rheumatism is a disease which usually occurs more than once in the same person. We gain nothing by referring the occurrence of rheumatism to a preceding rheumatic diathesis." He "ventures entirely to deny that, apart from actual morbid events, either present or past, from hereditary taint or from such probabilities as exposure to disease from age, or sex, or occupation, that it is ever possible to predict the future advent of disease." Here, again, we seem involved in what is virtually a question of language. To say that an individual has a "tubercular diathesis" is only a short mode of expressing the facts that he has certain peculiarities of structure or function which experience shows are common antecedent conditions of tubercular invasion. Thus guarded, such a word as "diathesis" may serve a useful purpose; but we quite agree with the lecturer that the field of "diathesis," "dyscrasia," "temperament," &c., has been one of the happy hunting-grounds of false science.

The lecturer deals at great length, and with signal ability, with such questions as the influence of sex, age, occupation, climate, and race upon the etiology of disease. We cannot follow him into all the interesting questions which he raises. We may just note that he denies that gastric ulcer and pernicious anæmia are of more frequent occurrence in the female than in the male sex—as has so often been asserted; that he repudiates the idea that any change of climate has taken place during the last few hundred years; that he ridicules the notion that overwork, physical or mental, is a common cause of disease; that he does not accept the widely prevalent idea that there is any greater nervous wear-and-tear now than formerly, or that nervous disorders are on the increase.

Dr. PYE-SMITH, in his last lecture, discusses fully the etiological relations of such important diseases as chorea, phthisis, lardaceous disease, gout, rheumatism, osteo-arthritis, and some forms of dermatitis; but we must refer our readers to the original for information on these points. We have said enough to illustrate the value of these lectures. They will attract all thoughtful practitioners, especially those interested in taking a really philosophic view of the complex problems of disease.

EVERY surgeon is now familiar with the little dimple in the skin so frequently found in the crease between the buttocks over the tip of the coccyx or higher up over the lower end of the sacrum. It is usually called the "post-anal dimple." It varies from a very faint depression up to a deep dimple, which has been even compared in appearance to the anus, and when all forms and varieties of it are grouped together it is certainly a very common malformation. It is of no clinical importance, but it has great scientific interest, and many theories have been suggested to account for it. It has been supposed to have some connexion with the post-anal gut and the neurenteric canal, and another view is that it is the cicatrix of the spina bifida by which the human tail has been lost.

Of much less common occurrence are sinuses opening in the same situation and running upwards close to the coccyx or sacrum in the middle line, perhaps for an inch or so. These sinuses often have a very tiny aperture, and occasionally more than one opening is found. They may give rise to no trouble of any kind, and be only accidentally discovered; but at other times they become inflamed and suppurate, and then may give rise to a good deal of trouble, especially if their true nature is not recognised. For the suppurating tract remains open in spite of all ordinary surgical measures. Very commonly hairs are found in these sinuses, often growing from their interior, occasionally lying loose in their interior, and then they are stated to be hairs from the skin around, which have been pressed into the sinus by the friction and pressure of the clothes. These hairs are often supposed to be the cause of suppuration and of the obstinacy of the inflammation when once set up, or rather of the difficulty experienced in getting the sinuses to heal up. But the most important anatomical fact is that they are in all cases lined with epidermis, and it is this circumstance which throws light upon their origin and also upon their clinical peculiarities.

Occupying the same situation cysts are occasionally found, with a wall of thin skin, and usually containing fine hairs as well as fluid matters and fatty débris. It is easy to see the connexion between these cysts and the sinuses just referred to; alike in origin, the sinus has remained connected with the skin covering the part often by a very narrow orifice only, while the cyst has become entirely detached from it. We have the same association of sinuses and cysts in the neck in the situation of the branchial clefts. The most common explanation of the cause of these sacro-coccygeal sinuses and cysts is that they result from the imperfect closure of the lower ends of the dorsal laminæ of epiblast which rise up to enclose the neural canal. Their median position, their epiblastic origin, as shown by the nature of the lining of the cysts and sinuses, and the fact that the dorsal laminæ unite latest of all at the lower extremity of the spinal canal, all support this view. Quite recently, however, a slight modification of this view has been suggested by French and American observers, who, working quite independently, have arrived at precisely the same facts and conclusions. It is well known that in the early stage of its development the neural canal and the spinal cord extend the whole length of the trunk of the embryo, but that as development proceeds the lower end of the spinal cord recedes from the caudal end of the trunk, until at birth it is opposite the third lumbar vertebra. This has been usually attributed to the more rapid growth of the spine than of the spinal cord contained within it. With the object of throwing light upon this question, MM. G. HERRMANN and F. TOURNEUX in France and Dr. MALLORY in America have examined transverse sections made through the sacro-coccygeal region of fœtuses at different periods of development, and they find over the coccyx epithelial-lined tubes which are larger and more perfect in the earlier stages, smaller and more fragmentary in the later stages, of development. These canals and tubes are lined by epithelium, some-

Digitized by Google

times distinctly squamous in character, sometimes prismatic; the cells showing a tendency, on the one hand, to develop into cuticle, and on the other hand, to develop into those of the spinal cord canal. It seems clear, therefore, that the lower end of the medullary canal is gradually obliterated as the fœtus develops, that this obliteration takes place irregularly, and that it is most often incomplete at the lower extremity. A failure in this obliteration produces either a cyst or a sinus, and the post-anal dimple must be regarded as a depression over the spot where the medullary canal and the surface epiblast were last of all in direct communication. Such a view is more in harmony with the general facts of embryology than the older notion of the disproportionate rate of growth of the spine and the spinal cord, and it explains in the simplest way the occurrences we are considering.

We have already mentioned that the sinuses over the coccyx are often very troublesome to treat. There is only one way of properly dealing with them, and that is by a deliberate and careful excision of the whole of the sinus wall. If even a small fragment of this is left failure may follow, and as these sinuses run deep, close to the bone, great care is often needed in this little operation. The cysts must, of course, be treated in a like manner. The analogy between these coccygeal dimples, sinuses, and cysts connected with the obliteration of the medullary canal, and the white spots, dimples, sinuses, and cysts connected with the closure of the branchial clefts is very striking.

"KNOWLEDGE comes, but Wisdom lingers," says the Poet Laureate, and, by something like the irony of Providence, it is in the field of Education itself that the truth of the saying is most pointedly exemplified. Here has knowledge been telling us, in tones the least mistakable, that in woman the physical substratum of the mental processes differs specifically from that in man, yet, deaf to the direct teaching of wisdom, we ignore this difference and we force the developing mind of the one sex into the mould prepared for that of the other, in fond expectation that the outcome of both will be equal, and that the distinctive features impressed by nature upon each will disappear in the educational laboratory. This disastrous procedure has scarcely been long enough in working to evolve its no less disastrous consequences. Little more than a generation has elapsed since the ill-inspired initiative of amiable but half-enlightened enthusiasts essayed "the intellectual equalisation of the sexes." But even already we have had indications of the Nemesis awaiting persistence in the attempt—indications which more than justify the mental physiologist and the truly scientific educator in agitating for its prompt and definitive abandonment.

Not for the first time, as these columns can too significantly attest, has the warning been given against the forcing system to which girls are subjected in so-called high-school education; nor has it anywhere been more authoritatively conveyed than by Sir JAMES CRICHTON-BROWNE. On Monday last, before the Medical Society of London, he returned to the theme—none the less opportunely, as the system he so strenuously opposes threatens to fructify in what CARLYLE has designated as "diseased developments" in literature and art, even in politics and religion. His oration, indeed, had but one fault, and that in its having been delivered to the auditory that least required its lessons. Interesting and, in some important respects, novel as were his demonstrations of the differentiating characteristics of the brains of the two sexes, it was to the so-called "educationist" rather than to the medical man, that they should have been addressed. The profession already knows, though its knowledge may lack the precision born of Sir J. CRICHTON-BROWNE'S experience in the deadhouse and the physiological laboratory, that the man's brain is not only heavier than the woman's, but that in weight it has a wider range of variation; that the distribution of the brain matter differs in both, the parietal lobes corresponding with the motor area of FERRIER being larger in the male, while the occipital lobes, which are sensory in function, are larger in the female; that the grey substance in the woman's brain is so inferior in density to the same substance in the man's as to mean, in her case, a less highly nourished, less highly developed organ; and that, finally, the circulation is more richly supplied in the male to that region of the brain which underlies volitional, cognitive, and ideo-motor activity than it is in the female, in whom, on the other hand, the sensory region is the more abundantly flushed with blood. These truths, recognised by the profession, though once again brought before it with admirable lucidity and force in the oration at the Medical Society, are, we repeat, so imperfectly realised by the educationist that it is on him by preference that they ought to have been inculcated, as it is by him, be it remembered, that the task of forcing the girlish mind has been assumed or rather usurped. Once let him fairly grasp the deep-seated differentiation in brain tissue and in brain function between the man and the woman, and we will do him the justice to say that his attempt to equalise their mental evolution would not survive the revelation. A change, if not an absolute reversal, of plan will then be his course, and with it an avoidance of those evils which, even if the plan were successful, would far outweigh any advantage so artificially won.

We need not follow Sir J. CRICHTON-BROWNE in his exposure of the many pathological results of the non-natural system of education which he combats, carried on as that system is under over-pressure. He tells us, what indeed is becoming notorious, that the more intelligent heads of girls' high schools are themselves awakening to the risks and positive evils of which they have been the unconscious instruments. So alive to these have many of them become that they seek for palliatives in the form of physical or even athletic exercises—again betraying ignorance of those physiological truths the disregard of which must prove fatal to all systems of education whatever. As Professor MOSSO has in his classic work, "Sulla Fatica," demonstrated, it is the most pernicious of mistakes to suppose, or to act on the supposition, that by substituting gymnastics for study during an hour or so of the day rest can be secured for the brain, and with it a greater alacrity and ability to resume head-work. We are glad to see Sir J. CRICHTON BROWNE adds his authority to that of the Turinese physiologist, and warns the conscience-pricked educationist that games, gymnastics, *a fortiori* drill, commendable in their proper place, will bring no tolerance of over-pressure or counter-

Digitized by Google

balance its evils. "A man who has been standing on one leg for some time finds it a relief to change to the other, but the expenditure of nervous energy is going on all the time, and the brain that is wellnigh drained dry needs rest, and will not be replenished by merely altering the channel of outflow." As to the contention that woman possesses resources physical and mental which might yet be evoked and developed by discipline hitherto denied her, the answer is not less clear. Not promiscuous work, and that in excess, for the attainment of a non-natural and impossible ideal, but carefully selected and normally graduated work for the harmonious evolution of faculties peculiarly woman's own, is that which must be imposed by the educator of the future. It is vain to appeal to the exemplars, historical or legendary, of feminine proficiency in support of the hotbed system now in favour. A PORTIA in law, a TROTULA in medicine, a MARY SOMERVILLE in physics, are exceptions which it would be idle to force the generality of their sex to rival—exceptions favoured by organisation in the first instance, by special often accidental circumstances in the second, which the educationist cannot create at pleasure. "Woman," says the great singer we have already quoted, "is not undeveloped man but diverse"—most estimable when her diversity is, normally, most pronounced. Harmony in variety is the growing need of our civilisation; not the dead uniformity which JOHN STUART MILL, after doing so much to bring it about, came in his latter and better moods to deplore. Identity of conditions and environment is working too efficiently to induce identity in the human product—man becoming more and more the mere double of his fellow man. Are we to reinforce this tendency at the very time when it most needs correction by a strenuous and over-strained endeavour to equalise woman with her male complement? Such is not nature's manifest design. Even already persistence in the attempt is evoking the protest of physiological law, and the sooner the false idea that inspires it is replaced by the other and the true one the better for the generation that is rising around us and for the generations that have yet to be.

THE *Pioneer Mail* of April 14th has several paragraphs referring to the occurrence of cholera in India in connexion with the Hurdwar fair. The subject is one of great importance and of no little difficulty. Seeing that outbreaks of cholera have so frequently taken place at these immense gatherings, the question has been often asked why the Government of India does not stop these fairs altogether. That is a question easily asked, no doubt, but it would be a most unpopular measure for a Government to prohibit them. It is a great Hindu religious rite. Vast crowds of pilgrims, full of fanatical zeal, will make almost any sacrifice and run any risk to attend these fairs, and no Government likes to incur the odium or face the consequences, which would be serious and might even be disastrous, of abolishing them. The Government has to accept the situation and do the best it can by making the most practicable arrangements and taking all the sanitary precautions in its power; and, to do the Government justice, it spares no pains in these respects to accomplish its ends, and meets not infrequently with success. There were only two or three cases of cholera at the Hurdwar fair last year, although, as Dr. W. J. SIMPSON has informed us, cholera bacilli were found in the water of the bathing pool; whereas, at this year's fair, the disease appeared in an epidemic form, and the action taken by the authorities was to disperse the pilgrims. It is stated that the climatic conditions of this year's fair were of an exceptional character. The pilgrims go to Hurdwar from all quarters and from immense distances. The railway had brought 40,000 pilgrims, and they were still coming by thousands when the fair was broken up, and some 70,000 pilgrims were hurried away from the bathing place at Hurdwar. It is stated that some of the bathers stricken with cholera were taken from the stream only to die a few minutes afterwards. The unfortunate people are dominated by religious fanaticism and fatalistic belief. The action of the authorities in dispersing the pilgrims has been sharply criticised, as it is alleged that the disease was spread through the districts by the returning pilgrims. On the other hand, the *Pioneer Mail* asks what the mortality would have been if 500,000 pilgrims, wearied and fatigued by their journey, had assembled at Hurdwar and had been confined together on a relatively small area.

There are certain points connected with these gatherings and the prevalence of cholera which require to be studied and worked out with judicial care. Do the pilgrims bring the disease with them to Hurdwar, and are the country and hill villages in the vicinity of the fair quite free from cholera at the time of and before the fair? Has the disease shown any tendency or not to prevail among the populations occupying districts near Hurdwar at the particular season at which these fairs are held? How many of these gatherings have been attended with outbreaks of cholera and to what extent and in what respects did they differ from those fairs in which no epidemic occurred—e.g., as regards the numbers attending the fair, the climatic conditions, and the hygienic arrangements. When an outbreak of cholera occurs and the pilgrims disperse to their homes, suffering from and in numerous cases dying of the disease *en route*, to what extent have they carried the disease to others, and been the cause of its spread among those who have not attended the fair? Has an epidemic or an outbreak of cholera been originated in this way, or has the apparent spreading of the disease been attributable to a very small number of persons? What is wanted is a knowledge of the way in which the disease comports itself, based upon exact information as to what the facts really were, and recorded at the time, while they were fresh in the memory and capable of verification. When an enormous gathering of pilgrims has been cholera-stricken and dispersed, it is not so much whether *they* carry the disease and die of it as whether they give rise to its appearance or not in other persons and in the various directions in which they travel. There are, of course, a great many other points calling for investigation, but the opportunity offered by this Hurdwar epidemic of tracing out and recording the facts connected with its medical history will not, we hope, be lost.

There are two directions in which we may approach the study of cholera. The disease may be studied from the standpoint of the epidemiologist in its relation to time

Digitized by Google

and space and its progress and direction under given conditions, as in the case of the Hurdwar epidemic in question; or the disease may be regarded from the standpoint of the local, scientific, or clinical observer, who deals with the phenomena presented on a small scale, in their relation to individuals and their environment, within narrow and circumscribed limits of time and space. The latter is likely to be the more exact and fruitful method of investigation; but both methods are obviously necessary, and they are complemental of one another. We want such an exact record of facts and observations in either case as shall tell their own tale and point their own moral.

Annotations.

"Ne quid nimis."

THE INTERNATIONAL MEDICAL CONGRESS OF 1893.

THE Fifth International Congress of the Red Cross Associations of Europe, of which we have given some account, was eagerly embraced by the delegates of the signatory Powers as an appropriate occasion on which to give expression to a cordial greeting to Italy, in view of the yet greater International Congress she is to hold in 1893. Their spokesman was, fittingly enough, Dr. von Coler, representing the court of Berlin at the recent Red Cross discussions, to whom the Berlin Congress of 1890 owed almost as much of its happy issue as to Virchow and Lassar. We take this pleasing initiative of goodwill towards Italy as of the best augury for the mighty gathering of 1893, for which she is making preparations that of themselves must command a memorable success. By her own generous admission she has taken a leaf not only from the Berlin Congress of 1890, but from the great Hygienic Congress held in London last year, and will spare no effort to make her return for the hospitalities she enjoyed in the British and German capitals equally worthy of her people and of the august city on which her unity and independence have set their seal. She could have no better promoter of her approaching international symposium than her distinguished consultant Dr. Guido Baccelli, to whom Virchow at the Berlin Congress gave the heartiest "Glück auf" in the language which to Baccelli is almost as much his mother tongue as his native Italian: "Gratias ago Baccellio nostro amicissimo quam maximas ex intimo corde. Spero fore ut eum videamus in Capitolio virum consularem triumphantem!"

THE OATH OF HIPPOCRATES.

EVEN in these days of advanced evolution in medicine there are many matters connected with its fundamental principles which must retain a perennial interest. Opinions respecting these may be ancient yet not antiquated, of primitive simplicity and yet accurate and even scientific. Thus it happens that the antique fathers of our art have still a place among us which does not belong to a departed though honoured memory—the place of those who seem to live and to labour in the permanence of the work which their genius organised. For, notwithstanding defects of observation and instruction, there was more in early medicine than a mere chaos of irrational conjectures. Glimpses obtained through the scanty records of those times reveal many signs of an orderly system. Of such a kind is the light which has been cast upon the views of Hippocrates by Dr. F. R. Smith of Baltimore, in a criticism published in the Bulletin of the Johns Hopkins University on the professional oath commonly attributed to that eminent authority. We may remind our readers that, as with other and later pledges of the same kind, ethics form the substance of this declaration. For the spirit of professional brotherhood which it breathes, for its fearless and explicit denunciation of criminal practice in an age when this was prevalent, for its portraiture of the practitioner as a model of regimen, and for the wise discretion enjoined upon him in his relations with his patients, the oath might still be studied with advantage. It is worth noting, too, that "precept, lecture, and every other mode of instruction" embodied the Hippocratic idea of medical education. In that day, as in our own, theory and practice, the book and the clinic, constituted the essence of true studentship. An expressed objection to the performance of lithotomy affords an early sign of the deepening cleavage between the provinces of the physician and the surgeon. The father of medicine doubtless acted wisely in advising the division of a labour destined to become colossal. We feel assured, however, that a mind like his could not have rested content within the far narrower limitations approved by modern specialists. He would rather have agreed with those practitioners of wider views who, recognising the finite conditions even of disease and treatment, are equally careful to apply, under sanction of time and opportunity, every particular means of relief, while duly maintaining touch with all vital conditions of a more general character.

THE SMALL-POX TRAMP AND HIS LESSONS.

THE fuller accounts which we have received of the unfortunate tramp with small-pox who applied at the Denbigh Infirmary, and of his treatment there, in no way improve our opinion of the sanitary and Poor-law authorities in that town. The case is very instructive as to the protection of those who rely on what the people of Leicester believe in—namely, sanitary police. The man had come unchallenged from Liverpool, after attending the races. On his way he stopped at Ruthin three or four nights, with the eruption upon him. He stayed for one night at Denbigh in a common lodging-house before presenting himself at the infirmary. It is not pleasant to think of the number of people who may have been infected during his journey. But the serious part is that when he reached Denbigh Infirmary, and the disease was duly diagnosed and notified to the sanitary authorities, they replied that they had no power to deal with it. They have since made up for their inaction by strongly denouncing the infirmary authorities for not keeping the man in, though obviously the infirmary was not a fit place for the detention of such a case. In fact, it would have been cruel to the rest of the inmates to detain him there. He was, in the language of the Act quoted by the Mayor of Denbigh in his letter to us last week, most "improperly housed"—that is, he was housed where infection was sure to spread quickly to already afflicted people. The case was a modified one; and after being detained several hours, to give the sanitary authorities time to make provision for him, he was told that he could not be treated there. The sanitary authorities ultimately succeeded in getting shelter for this poor fellow in the common lodging-house he had slept in the night before! A sanitary authority has no excuse for being found so unprepared as in this case. It has had years to prepare a place of isolation for such cases, and it has been sleeping all the time. When the inevitable need arose, it proved as deficient in resource as it had been in providence. Surely in a town of 6000 inhabitants a better place than a common lodging-house could have been found in six or eight hours. Let us hope that the other authorities of the

Digitized by Google

country are not folding their arms in this fashion with no conception of energy except for the denunciation of others for not doing what they themselves should have done. We are not very hopeful on this point. The accounts of outbreaks in other places are not reassuring. The dreaded disease has been in such abeyance of late years that sanitary authorities have been neglecting their duties, and playing into the hands of anti-vaccinationists and other faddists. Now it looks as if a great test would soon be applied to them. All sensible people will see to their own protection. Those who do not are at the mercy of tramps who traverse the country unwatched, and of those whose interest it is to keep the disease concealed till it passes all bounds.

THE DISPOSAL OF STILLBIRTHS.

CASES showing the necessity for some change in the laws relating to stillborn infants occur with alarming frequency. Not long ago the county coroner for the West Derby district of Lancashire held an inquest upon the body of a deceased infant whose mother had tried to have it interred as a stillbirth, although it was the second child she had given birth to, both being illegitimate. More recently the same coroner held an inquest at St. Helens upon the body of an infant which was found in the possession of a local midwife. Whether it was stillborn or deceased could not be ascertained, as so much time had been permitted to elapse since its birth and discovery that decomposition was far advanced. Within the last few days we see reported a "burial scandal" at Strood, near Rochester, where it appears that a gravedigger, to save himself trouble, had, instead of digging a grave for the burial of stillbirths, deposited them in other persons' graves—a most reprehensible proceeding. The registration of stillbirths in this country appears to be as far off as ever, in spite of all that has been urged in THE LANCET and in the lay press. So long as it continues to be the law of the land that stillbirths are not to be registered, it becomes all the more imperative that their burial should be surrounded by every safeguard. This is evidently not the case now. A separate portion of each burial-ground should be set apart for these interments, the graves should be numbered, and there ought to be no difficulty in identifying that one in which any particular burial has taken place, and in exhuming the body within a reasonable period, should any circumstances render this desirable.

THE PHYSIOLOGY OF DREAMS.

AMONGST those who crowded the theatre of the Royal Institution last Friday evening to listen to Dr. B. W. Richardson's lecture on the "Physiology of Dreams" there were probably some who expected to hear of miraculous and mysterious events of dream and trance, whilst others would expect to receive from the discourse nothing more and nothing less than the latest views of a man of science on the subject of dreaming treated from its scientific side. The last-named had their way, for the lecture, although so prepared as not to be wanting in general interest, was exclusively an exposition of the phenomena and causes of dreams from the scientific side alone. There is no mystery in dreaming, it was contended, that is not already explainable on physical grounds, or that does not admit of being explained as investigations on purely physical methods progress. The phenomena of dreams were first discussed, and were classified under three heads. There are dreams which are entirely objective, brought about by the effect or effects of some external object or action; an external vibration acting upon the corporeal vibratorium. There are subjective dreams, dependent on some vibration occurring within the body itself, and carried by nervous conduction to the sensorium. And there are, thirdly, dreams due to a combination of the objective and subjective influences. These different kinds of dreams the lecturer defined from particulars which he, from his long experience in professional life, had noted down; and many details of a most interesting character were thus supplied. The dreams of fever, of indigestion, of exhaustion, of pain, of melancholy, of fear, of contention, of motion, of narcotism from inhaling different gases and vapours, and of circumstantial reasoning in sleep, were noticed and exemplified, the evidence in each case being to the effect that an external or internal influence was sustaining by vibration the condition of dream, and that such condition differed only from the waking dream in that it was less perfect and complete. In the second division of his discourse Dr. Richardson dealt with causes of dreams, in which he maintained that the dream is a purely physical phase of life; that it depends on two conditions, our own corporeal organisation, and the state, for a time, of the surroundings of our life. There is no more of mystery, of potency, of prescience, in the dream of sleep than there is in the dream of the wakeful day. We dream according to our nature, our habit, and our environment. Dream is a partial mental activity combined with a more or less complete physical repose. In illustrating this part of his subject, Dr. Richardson, from a series of beautiful plates, showed on the screen the parts of the nervous system directly or indirectly concerned in dreaming. Three of these, of the organic nervous system, were direct photographs from natural parts; another was from an original plate of Vesalius, rendering that great anatomist's view of the pneumogastric nerve in its course from the brain to the heart and stomach; and another still, showing the arterial skeleton, was from the famous drawing by Albinus. The mode in which vibrations could be carried from the external world through the senses to the sensorium, and from the viscera to the same centre, was in this manner delineated, and the cause of the objective and of the subjective dream made clear. A series of practical deductions brought to a close a lecture which came quite naturally within the domain of medical science, and yet from its every-day experience admitted of being discussed in a method perfectly understandable by a general audience.

THE ABUSE OF COCAINE.

MR. CONOLLY NORMAN of Dublin contributes a paper on this subject to the last number of the *Journal of Mental Science*. He says that undoubtedly much harm has resulted from a recent tendency to use cocaine as a help to break off the morphia habit, and from the mistaken notion that this drug can be employed safely and advantageously for this purpose. Cocaine, the author remarks, is more insidious than morphia; it fastens upon its victim more readily, and its hold is at least as tight. The special dangers of cocaine are said to be three: (1) That it is treacherous; (2) that it early produces breakdown, both in the moral and intellectual spheres; and (3) that it is intensely toxic, bringing about destructive tissue change after a comparatively short period of abuse. In the last respect it differs from alcohol and morphia, which may be long indulged in, in considerable quantities, without giving rise to serious structural change. In chronic cocaine poisoning, on the other hand, marasmus appears early and develops with extreme rapidity, convulsions are not uncommon, and chronic poisoning in animals produces, as Zanchevski has shown, degeneration in the cells of the medulla and spinal cord, and also in the nerve cells of the heart ganglia, and in the liver cells. The great danger of cocaine lies in the fact that it is the most agreeable and alluring of all narcotics. It causes no mental confusion, only a little more talkativeness than usual, the narcotic effects are not overwhelming, and there is no head-

Digitized by Google

ache or nausea, and the pleasant effects are produced with a comparatively small dose. But toxic symptoms are rapidly developed, and within three months of the commencement of the habit there may be marked indications of degeneration, loss of memory, hallucinations, and suspicions. Dr. Norman has seen three cases of abuse of cocaine. In one the drug was given as a substitute for morphia, in the second it was first given for a painful affection of the nose, and in the third the patient was in search of a new stimulant. The symptoms in the first case were hallucinations, sexual excitement, and loss of sense of the passage of time. The second patient was elderly, and, after six months' use of cocaine, he fell into a state of mental hebetude, with loss of memory and broken irregular sleep. He was also tormented with sexual excitement. In the third case, a young man, the memory was failing, he was furtive and shifty in manner, and could not speak the truth. He also had visual hallucinations, and at first sexual desire was increased, but latterly diminished. These cases seem to furnish fair examples of the usual condition produced—a condition sufficiently serious to put medical men on their guard against prescribing too freely a drug so insidious and so dangerous.

THE INAUGURAL BANQUET OF THE ROYAL ACADEMY.

THE First Lord of the Treasury, in reply to Sir F. Leighton's toast of "Her Majesty's Ministers," touched felicitously on some of the blemishes of London life which time seems to intensify rather than diminish. "When almost every right of property," he said, "is criticised by somebody or other," there is one which is left unquestioned, "the right of every man to erect on his own ground the most hideous and shapeless structure of discoloured brick which may suit his commercial instincts—structures which even the hand of time will never render tolerable, and which even decay cannot make picturesque." While Mr. Balfour, parodying the well known aphorism of the late Archbishop of York, would rather "that Englishmen should be free than that Englishmen should be æsthetic," he is surely more than justified in his protest against the desecration of such noble sites as the margin of our "silent highway" by buildings that embody nearly every architectural fault. He had the edifices between Charing-cross and the river especially in view, the railway station with "the bridge that is appended thereto" being at once "an eyesore and an insult" to the citizens of London, who are, however, powerless to prevent such monstrosities before they become *faits accomplis*. A better cultured public taste finding expression through a more perfectly organised public opinion is the remedy we must look to, though the combination of the two in civic life is as yet remote enough. Art and literature have still much to do before that consummation is reached, but if we may believe Sir F. Leighton and the accomplished Hellenist, Professor Butcher, whom he associated with the toast of "Literature," the two main factors of improvement in æileship are beginning to work in the desired direction. Professor Butcher dwelt convincingly on the need of a still better understanding between literature and science than has of late years been manifested—literature insisting too exclusively on the claims of form, science on those of substance. That the two are not incompatible,—that when each is at its best they are found blended indissolubly—he had no difficulty in illustrating, particularly from those ideal *chefs-d'œuvre* which abound in the language he teaches. "The Greeks," he says, "were able even to make science literary and to produce a treatise on medicine which bears the stamp of the great masters of language." This is admirably true, and the physician who is also a man of letters could supply instance upon instance from the Greek, and even the Latin, writers on medicine, to whom the remark might apply. Take the first treatise in Littré's edition of the Hippocratic collection, that on "Air, Water, and Locality," and the reader will not have gone far before he feels himself under the guidance of a true artist in words as well as of a true genius in science. The description of impending dissolution, known to all time as the "facies Hippocratica," could have been spoken or penned by no one but a physician who was also a painter in language. Even the patrician dilettante in medicine, the Roman Aulus Cornelius Celsus, had so much in common with his master, Hippocrates, as to have drawn a picture of epilepsy which survives in our medical classics and inspires a memorable page in Sir Thomas Watson's "Practice of Physic." But of all Greek medical writers who have made a professional treatise a masterpiece of language the one whom Professor Butcher had doubtless in his eye was Aretæus, who, though as late as the second century, wrote in the purest Ionic Greek, and has left us a gallery of pathological portraits which distinguishes him as the Æschylus of medical delineation. He is, according to Paccinotti, the most tragic, in the dramatic sense, of our professional masters, as may be seen on a perusal of his work in the original edited by Dr. Francis Adams, or even in the same scholar's own translation, to say nothing of its brilliant rendering in Italian by Puccinotti himself.

SUICIDE DURING PARTURITION.

ALTHOUGH the pangs of labour are severe, and the dread of operative interference is great with some women, yet it is most unusual for a parturient woman to commit suicide. Recently, however, a case occurred in Wigan where the woman—after some hours of labour, and upon the midwife telling her that it would be necessary to have the aid of a medical man, owing to its being a breech presentation,—whilst the husband went for the doctor left the house, notwithstanding the protestations of the nurse, and when the doctor and husband returned she was nowhere to be found. The medical man waited some time while a search was made for her, and then left. Next morning her body was found in the canal with the newly born infant. The shock produced by sudden immersion must have caused the uterus to expel its contents. The woman had not far to walk, and it seems probable that she had previously planned her self-destruction. An inquest was held, and the jury returned a verdict of suicide whilst in an unsound state of mind.

SURGICAL TREATMENT OF EPILEPSY.

DR. SACHS of New York has contributed an interesting and suggestive paper on this subject to the *New York Medical Journal*, and an abstract appears in the last number of the *Neurologisches Centralblatt*. He is inclined to regard primary or so-called idiopathic epilepsy as a somewhat more uncommon affection than it is usually supposed to be, being of opinion that many such cases are really the result of accidents which happened years before any symptoms appeared, and that some of them are the consequence of cerebral lesions in infancy. He adheres to the views of Marie, Fé é, and Chaslin that the pathological equivalent of epilepsy is a sclerotic condition of the cortex which leads to a disturbance of the functions of the cells, and this sclerosis he regards as the result of some preceding traumatism. Months or even years may elapse, however, before the sclerosis has advanced sufficiently to give rise to discharges. From these views as to the nature and origin of epilepsy his therapeutic views are naturally enough deduced—viz., the removal, or impairment of the activity of the original irritant, or

Digitized by Google

the prevention of the secondary sclerosis or the neutralisation of its effects. In other words, where there is an injury to the skull or a hæmorrhage in the cortex immediate operation is desirable; and if the symptoms of secondary sclerosis are already present, then removal of the affected cortex must be carried out. But, as Dr. Sachs remarks, the limits of the sclerosis are not easily defined, and he even urges immediate operation for any skull injury. Of his four cases of operation for epilepsy only one was notably improved, but he had better results in cases of epilepsy, the result of injury in childhood, in which operation was undertaken. The three cases which he records were much improved, the epileptic attacks remaining absent for three or even six months at a time. There is no doubt that the opinion is gaining ground, and may now almost be regarded as a surgical axiom, that at least all cases of depressed fracture, whether producing symptoms at the time or not, should be operated upon; but whether this rule should be extended so as to include even slight skull injuries, it is as yet not easy to decide. The dangers of head operations are now reduced to a minimum, so that it may be said that in any case in which there is a probability of injury to the underlying cerebral structures operation is not only justifiable, but ought to be carried out.

PENNY FEES AT DISPENSARIES.

THE biennial dinner of the Finsbury Dispensary was recently held at the Albion under the auspices of the Lord Mayor. Five hundred pounds was the result, which the funds of the dispensary, depleted by the strain of the influenza and the operation of the City Charities Act, much needed. This satisfactory result was due very much to the effective eloquence of the Lord Mayor. There is only one sentence in his lordship's speech which we feel disposed to criticise—the payment of a penny by the patients for medicine or advice. The Lord Mayor approved this rule as likely to give the poor some sense of being not altogether objects of charity. The rule has been adopted by many other dispensaries. The moral virtue of the payment is doubtful. As a standard of the value of medical services it is decidedly objectionable, and has perhaps something to do with the fact that in free dispensaries the medical officers get nothing, and in provident dispensaries a very poor remuneration.

PRISON REFORMATORIES AND THE INCREASE IN CRIME.

THE American system of prison reformatories is on its trial. So far it cannot be said to have proved a success if we are to judge of this from evidence of a reduction in the number of the criminal population. According to statistics quoted in a recent publication of the Howard Society the proportion of law breakers in the United States, which in 1850 was 290 per million, stood in 1880 at 1169 per million, and there is too good reason to believe that it has now reached a still higher level. At first sight it may seem extraordinary that crime, a disorder of the social system, should not have proved more amenable to such curative efforts as those put forth by the authorities of the institution at Elmira, yet these attempts, in the opinion of many experienced and careful thinkers both in this country and America, have not only failed to realise their proper object, but have been directly instrumental in promoting the increase of crime already referred to. This view, there is unfortunately reason to believe, is not unsupported by reliable proof. For the explanation of this fact we must search into the constitution of the reformatory system. As regards the wholesomeness of the reform contemplated by this agency there can hardly be two opinions. Clearly the mere infliction of punishment has not so far done more than check the lawless outbursts of criminal instinct. It is evidently inefficient for the purpose of reformation, and the methods applied at Elmira and elsewhere are so many tentative endeavours to arrive at a more truly remedial form of treatment. Unfortunately those methods leave much to be desired. Founded on a law of kindness, they have been indiscreetly genial in operation. The criminal, no matter how guilty, once within the walls of the reformatory lacks nothing of comfort or convenience save his personal liberty. He is well lodged, well fed, has recreation in varied plenty, work which is not always compulsory, and food of superior quality in abundance. He is allowed free communication with his fellow prisoners, notwithstanding the fact that this has often proved in the history of prison management a source of moral contamination. The tendency to this latter evil is combated, but surely it cannot thus be effectually overcome, chiefly by means of education imparted in the form of lectures, book study, &c. Religious training is not excluded, but its place among the customary usages of the reformatory is not a prominent one. Thus the agent which, however we explain its power, has been found the most potent in regulating conduct remains too little utilised, and its place is filled by the feebler presence of a lecture-code of moral axioms. It is to indiscretions like these that we must ascribe the comparative unfruitfulness of the prison reformatory system. If, therefore, we would enjoy its best results, we must alter its methods. Justice demands that crime shall bear its penalty: prison life must be of a kind rather to repel by severity than to attract by luxury.

INFLUENZA AND THE POSSIBILITY OF AERIAL INFECTION.

DURING the late epidemics it occurred to us that the most valuable evidence with regard to the possibility of the spread of the epidemic through the air might be obtained from some of the isolated lighthouses on our coast. Cases of influenza having been reported both at the Bishop's Rock lighthouse (off Scilly) and at the Caskets lighthouse (off Alderney), we placed ourselves in communication with the medical officers who attend the residents on those lighthouses, and have to thank them for their replies to our queries. It is clear from these replies that no sufficient proof of aerial infection has been established. As to the Bishop's Rock lighthouse it s very questionable whether the first case reported was really a case of influenza. With regard to the Caskets, there is no question that some of the attendants suffered from the epidemic; but inasmuch as fishing-boats from Guernsey, Jersey, France, and England very frequently called—especially from the first-mentioned place, where influenza has been very prevalent,—it is impossible to feel assured that the infection was not communicated directly from persons infected with the disease. It seems to us of the greatest importance, in view of the opinions which are held as to the mode by which this disease is spread, that these points should be definitely put on record, as the older investigations as to the spread of this epidemic at a distance are not altogether trustworthy.

CHLORODYNE.

THE numerous fatal accidents resulting from the sale, without any warning of their dangerous properties, of preparations containing opium or substances derived from opium, render the action of the Treasury in connexion with "Dr. Collis Browne's chlorodyne' peculiarly necessary. As a result of several coroners' inquests and of representations from various quarters this preparation has been officially tested, and a prosecution has been very properly instituted against

Digitized by Google

the manufacturer rather than against any small retail shopkeeper, who might plead ignorance. That the case was regarded as one of considerable importance may be gathered from the array of eminent counsel employed. It was contended that chlorodyne was a proprietary medicine, and that the manufacturer had to take out an Excise licence and pay a stamp duty on every bottle. From a legal point of view a great deal appeared to depend upon whether the substance was a patent medicine or not. The prosecution maintained that the bottles should be labelled with the word "Poison," so that the public should know what they were actually buying when purchasing medicines containing a certain amount of poison, and children and adults with a tendency to commit suicide should be unable to obtain such dangerous drugs. For the defence it was urged that chlorodyne had been sold for over forty years, and that it was unwise to employ the word "poison" as it would tell people what to take if they wanted to commit suicide, and indeed that it might be safer to keep it as a medicine, as everybody disliked medicine, and the young particularly shrank from taking that which they knew to be a medicine. This curious contention strikes at the root of the matter, and questions the wisdom of the provisions of the Sale of Poisons Act. As a matter of argument, it may be admitted that for the purposes of suicide the red label appears to offer certain facilities; but it is relatively so easy to procure poisons that surely the true purport of the label is to protect the public against accidents through ignorance. For a medicine, even a patent medicine, containing 15 per cent. of chloroform and two grains to the ounce of morphine, to be retailed without any warning, all over the country, by drapers, grocers, and chandlers, is surely to invite accidents. The medicinal value of chlorodyne is not here in question—indeed, there is an official preparation much resembling it in the British Pharmacopœia; but then it is intended for use under medical advice and for sale by qualified chemists, and it is not dispensed freely for general, unskilled, haphazard employment in the treatment of coughs, colds, fever, and the like, as though it were absolutely free from danger.

EX-CATHEDRA UTTERANCES v. SCIENTIFIC CAUTION.

THE admission of medical controversial matter into the lay press is always, we think, to be deplored, and we certainly regret that, when scientific questions are mooted, they are not handled in the way in which men discuss them who have received a training in science and have acquired the spirit of caution which illumines the *savant* but darkens the counsels of the ignorant. No subject has suffered more in this way than that of anæsthetics. Men, whose education should have taught them better, have, when astride of their favourite hobby, thrown logic to the winds, and have not stopped even at personalities in their endeavours to force all the round men of the earth into the square holes which fit their own ideas and experiences. In a recent issue of the *Bombay Gazette*, for example, the cudgels have been taken up about the use of chloroform, and statements have been made which are as ill-judged as they are unjustified by facts. Thus a correspondent signing himself "Buggobutty Bose" takes Mr. S. Harris, M.R.C.S., to task for his supposed ignorance of the work of the Hyderabad Commission. He goes on to say that professional opinion was, before the session of the Commission, divided between the views of London chloroformists and those of Edinburgh, the former always taking the pulse as the guide, the latter always taking the respiration. He adds: "The Commission has proved that the Scotch method is right, and that to take the pulse as a guide to the effect of chloroform is unsafe. *It is therefore criminal.*" The italics are ours. The quotation reveals ignorance of the methods of London schools, which the discourteous sneers contained in the letter make the less excusable. The practice of London anæsthetists has been more than once put before the profession in our columns, and it is only fair to say that they attach quite as much importance to watching the respiration as the followers of Simpson and Syme. They differ, however, from them in believing that in human beings cardiac syncope may occur in various stages of anæsthesia, and that such an occurrence is not due to primary respiratory failure. Holding this belief, they consistently teach that the pulse should be watched *as well as* the respiration. It is not within our province to decide for one party or the other, but we must emphatically deprecate any aggressive writing on the part of disputants favouring one or the other view, especially when it does not stop short of preferring a charge of wholesale crime against the bulk of the English profession.

ANIMAL VACCINE LYMPH.

THE Local Government Board does not undertake to supply calf lymph to the profession for any other purpose than the vaccination of the first of a series of cases. Medical men have to rely upon their own efforts to maintain their stock of lymph, and as a result some private institutions exist in this country for the production of and the sale of calf lymph to those who desire to use it. We have had brought to our notice the institution which Dr. Hime has established at Bradford, and where he has evidently met with considerable success. The lymph is supplied in three forms—on points, in tubes, and as a conserve. Of the two first methods of preparation we have had ample experience in this country, but the use of conserve is limited, although in Germany and America it is much more commonly employed. The chief objection to calf lymph is that it must, if generally used, lead to arm-to-arm vaccination being replaced by vaccination with stored lymph, which has a less certain success. If Dr. Hime could obtain information as to the insertion success which attends the use of his lymph, the result would be of considerable interest. In the hands of many operators the skill of the vaccinators would no doubt vary, but this is equally true for arm-to-arm vaccination, and it would be well worth learning whether those who use calf lymph stored are less successful than when they vaccinate from arm-to-arm. Dr. Hime, in issuing his calf lymph, explains that it is impossible to collect it without some admixture with blood-corpuscles. This is undoubtedly the case, but after some years of experience of the use of calf lymph there is no reason to think that danger is caused by this circumstance.

THE VACANT CORONERSHIPS.

BY the death of Dr. Diplock another vacancy has occurred in the coroner's office, and we trust that those in whose hands the appointment of the coroners of Newington and district and of West London respectively rests will not have to look beyond the field of medical applicants for a suitable candidate to fill such important positions. The battle fought for the principle was toilsome and expensive, and the early results which followed upon the medical victory of 1838 are too obvious to students of forensic medicine and to those whose affairs lead them to deal with the coroner's court. The arguments in favour of the principle do not need to be reiterated in these columns. The battle was won on the strength of indisputable facts and indestructible arguments. We trust that the County Council of London will not dispossess the medical profession of an office which it has held so long with so much benefit to the general public. To

Digitized by Google

break in upon the direct succession of medical coroners of Middlesex, which commenced with the late Mr. Thomas Wakley, M.P., would indeed be nothing short of a catastrophe. Several candidates eminently suited to act in this capacity are, we understand, in the field. Among others, Dr. Wynn Westcott, who has acted as deputy-coroner for Central London and Central Middlesex for nine years, and who during his tenure of office has held more than 2000 inquests, offers himself as a candidate. We are also informed that Dr. Drew, who, in addition to his medical qualifications, is a barrister, and possesses testimonials of a high character as to his forensic ability and medical knowledge, comes forward as a candidate. We understand also that Dr. Grierson Gledhill, a Bachelor of Medicine, Master of Surgery, and Licentiate of the Apothecaries' Hall, and a member of the Northern Circuit, intends to apply for the vacant office. No doubt other medical candidates will come forward for the vacancies, and it is to be hoped that, in respect of the coroner's office, no retrograde step will be taken by the electorate.

RELIGIOUS MINISTRATIONS IN INFECTIOUS HOSPITALS.

THE contest still goes on in the *Surrey Advertiser* between the Rev. Mr. Fowler and other ministers of religion and those who claim for the resident medical officer a voice in the question as to the fitness or frequency of their visits. We have already expressed our opinion that those who have the cure of souls and those who have the medical care of patients should take note of each other's functions and the interest of the patient, not forgetting that in an infectious hospital unnecessary visits are a danger to the public. Reference has been made to the rules of the Fever Hospital in London on this subject. They are as follows:

48. Ministers of religion of all denominations shall have free and equal access to the hospital, but no minister of any denomination shall receive any payment out of the funds of the hospital in respect of his ministrations.

49. It shall be a standing instruction to the committee and officers of the hospital that any minister of religion desirous of visiting or ministering to patients of his own denomination shall be received with all courtesy, and shall be afforded all facilities consistent with the wishes and welfare of the patients and the convenient conduct of the hospital.

The first rule secures impartiality as between ministers of different sects and freedom of access; the second qualifies the facilitation of the visits of ministers by regard to the wishes and welfare of the patients and the convenient conduct of the hospital. It is obvious that the resident medical officer is the best judge, and the only available one of the medical aspect of "the patient's welfare," and should not be ignored. But we can quite believe, as we are informed by Dr. Hopwood, the resident medical officer of the London Fever Hospital, that he has always received from ministers of religion of all denominations the most courteous assistance in carrying out these rules.

THE OPIUM TRAFFIC IN ITS COMMERCIAL ASPECT.

IT was only consistent with the conditions of the case that the controversy relating to the opium traffic should be largely concerned with its moral and medical aspects. But for this fact, our own position with regard to it would be entirely different from what it is. At the same time, however, if we would appreciate the questions involved in their full significance, we cannot ignore their connexion with Indian commerce and finance. In the opinion of the Government of India, the time has not yet come when the substantial revenue accruing from this trade can safely be surrendered. No equal profit can be extracted from other sources of supply; no substitute method of taxation would prove as tolerable to the population. Such is the official position. That it is maintained with reluctance in the face of the ethical considerations above referred to we are willing to allow. It does not follow that it is impregnable, and it has indeed been assailed with some energy. Thus, for example, Mr. David McLaren, ex-President of the Edinburgh Chamber of Commerce, claims to have found in the opium traffic the true explanation of an admitted fact—namely, the disappointingly slow development of a general trade between this country and China as compared with that with other countries. He brings out in prominence the great disparity in this respect between Japan, where the importation of opium is prohibited and where British exports in 1888–90 realised £3,982,271, and her colossal neighbour, which spent only £8,451,908. His argument is briefly summed up in the words of a Chinese magistrate: "Cease sending us so much opium and we shall be enabled to take your manufactures." Considerable thought has likewise been devoted to the financial aspect of this question by Mr. Joseph Alexander in a paper entitled "Substitutes for the Opium Revenue." He directs attention to the gradual diminution of the opium revenue of late years in consequence of increased production in China, and he suggests that even if the profits reaching the Indian Exchequer from the sale of opium were entirely done away with they could not but be made good by other means. Among such are included the preparation of medicinal opium (an industry at present practically unknown in India), the cultivation of food crops in the opium-growing districts, and retrenchment in the services, both civil and military. He does not approve of the gradual diminution of the opium revenue, but advocates its immediate suspension. He would have this country allow the Indian Government as compensation a sum of £10,000,000 for the repayment of which and for the maintenance of Indian solvency he would rely upon the profits of increased trade with China and upon such measures of reform as those above mentioned. Clearly there is a good deal to be said for this presentation of the case, but we must for fuller details refer our readers to the paper itself. It is published, as is also that of Mr. McLaren, by Messrs. King and Son, 5, King-street, S.W.

THE PROCTORIAL SYSTEM AT CAMBRIDGE AND OXFORD.

AS might have been expected, the case known as the "Spinning House case at Cambridge" has brought into renewed prominence the peculiar powers possessed by the proctors and the pro-proctors of that University in dealing with prostitutes and other disorderly females in the streets, as also with any members of the University who may be found accosting or being accosted by them. These powers are conferred by a very ancient statute, and are undoubtedly of a somewhat arbitrary character. About thirty years ago there was an alleged charge of a respectable girl having been arrested at Cambridge, taken to the Spinning House, and having had her hair cut. Other cases of a somewhat similar kind have occurred between that and the most recent case, which ended in favour of the defendant, the Rev. N. Wallis, the pro-proctor who ordered the arrest. No other result could have been expected. Whether the proctorial powers were designed, *inter alia*, to prevent the spread of venereal and especially of syphilitic diseases among the undergraduates may be questioned, but that they have had the effect of preventing these diseases is beyond question, and it is this circumstance which has induced us to notice the matter. The civic authorities of Cambridge have by a majority petitioned for the repeal of the Act which confers these special powers upon the University authorities, while the latter have, even by a larger majority, petitioned for their retention. It is scarcely reasonable for the former to demand that the keeping of order in the streets so far as

Digitized by Google

regards women and their behaviour therein with undergraduates, should be left to the ordinary law, seeing what the result of this is elsewhere. Although it is an offence for any woman to "be loitering or to be in any thoroughfare or public place for the purpose of prostitution or solicitation to the annoyance of any inhabitant or passenger," in the words of the Act of Parliament; so sure as evening comes round will the streets of most cities and towns be the scenes of open violation of the law, the two of the only towns where the law is respected being Cambridge and its sister University city, Oxford, not by virtue of the ordinary law, but of ancient statutes. Writing on this subject some years ago in a daily paper, a clergyman indignantly observed, "Our magistrates should exercise the law—should clear the streets of every one of these infamous women, and make them at least decent, if they cannot make them moral and virtuous." Sir William Jenner observed, even more forcibly, "Law could do much to diminish the mortality from syphilis; it could prevent the prostitute from plying her trade in the public thoroughfares, and thus keep temptation to some extent out of the way of the merely irresolute and thoughtless. It is a disgrace to authority that it does not frame and put in force such a law." Oxford and Cambridge are at present free from this reproach, and it is to be trusted that they will remain so. Among so large a body of young men as are to be found any term in either University, there must be a certain proportion of the merely irresolute and thoughtless, and of the viciously inclined also. It would be easy to prophesy what would be the result of any abrogation of the proctorial powers. The ordinary uniformed police could not, in addition to their other duties, deal with the evil so effectually as a special police, not only in preventing immorality among young men and young women, but also in deterring the latter from being decoyed into a hateful means of livelihood.

THE TRIAL OF DEEMING.

FREDERICK BAILEY DEEMING, *alias* Williams, was put upon his trial at Melbourne on the 28th ult. for the murder of his wife about Christmas last. The counsel for the prosecution traced out the connexion of the prisoner with the crime with an amount of detail that left no link missing in the long chain of evidence that was forthcoming to convict him of the murder. The skull of the deceased had been fractured in several places and her throat cut, and the body had been buried under the cemented floor of the house in which they lived in Australia. No attempt was made to show that the prisoner was not the perpetrator of the deed, and the only defence that was offered was based upon the question of Deeming's sanity and responsibility for his acts. His counsel attempted to make out a case for the prisoner's insanity by a vigorous *ex-parte* statement. He claimed first of all that the evidence for the prosecution was wholly and solely circumstantial; and he went on to say that the prisoner had been punished as a thief and a bigamist, and that "if it were true that there was lunacy in the accused's family, that he was suffering from diseases which had been described to the court, and that he was labouring under an imperious mandate to commit murder, as prisoner imagined, by his mother, in a vision," the question which had to be asked was, "Is it possible to listen to all these statements and say this creature is human?" The evidence of the medical experts who were called on behalf of the prisoner's insanity was, like the statements of his counsel, of the most hypothetical and unconvincing nature, and we are not surprised that the jury, in returning their verdict of "Guilty," added a rider with the express statement that Deeming was not insane. The unwholesome and morbid craving for the sensational in crime that has manifested itself in this case of mere brutish appetite is almost the worst and most regrettable feature of its whole history, as having a widespread and destructive influence on the better feelings of individuals. From a medico-legal standpoint, there are many points connected with the case, and with the nature of the professional evidence given at the trial, that appear to demand further consideration and criticism. We hope to deal with these in an early issue.

SMALL-POX AT PEMBROKE DOCK.

SMALL-POX has broken out at Pembroke Dock, and in so far as adequate means of isolation are concerned, it seems to have found the sanitary authority quite unprepared. The medical officer of health, writing to the Local Government Board on April 25th, talks of the authority being then in treaty for a hospital. At the same time vaccination and disinfection have to a large extent been carried out, and it is stated that, although twenty-five cases have occurred, there have only been two instances in which multiple attacks in households have occurred. The latest intelligence is to the effect that no fresh cases are taking place

NOTIFICATION DEFECTS.

THE Act for the Notification of Infectious Diseases, like other Acts of a similar character, does not take effect as regards any building &c. "belonging to Her Majesty the Queen or to any inmate thereof." It is due to this that scarlet fever in the Exeter Town Barracks is not notified to the medical officer of health; and since the children from those barracks attend the ordinary town schools, some apprehension is expressed by the sanitary authority. We can quite understand that where Royal and Government departments are under the charge of officially appointed medical officers there may be no need for the intervention of the local health officer; but if notification returns are to be of real value they should be complete, and sanitary authorities who are responsible for public health ought at least to be apprised of disease which is going on in their districts, so that they may take any measures of precaution that may be necessary beyond the precincts of the buildings that happen to be exempt from the operation of the general law. The fact of the notification being necessary would be an additional guarantee that inside the exempted building the needed measures of prevention were being adopted. The point deserves notice in case of any amendment of the law as to notification.

THE FOOT-AND-MOUTH DISEASE.

NOTWITHSTANDING the efforts of the Government, this bovine affection still lingers in the country, its last stronghold being in Kent. Here it prevails among sheep, and appears most difficult to eradicate. The places where it is localised are completely isolated, as it were, cordons of police surrounding them, and no animals are allowed to leave the circle or zone drawn around them. If this vigilance is maintained the disease must be soon suppressed; but the invasion should convey a most salutary lesson in our live-stock dealing with infected countries. Notwithstanding the most careful inspection at the ports of debarkation of cattle from continental countries reported to be free from infection, this insidious malady has found entrance, and in spite of the elaborate, extensive, and expensive machinery at the command of the Government, which has full powers to deal with it, it has appeared in several parts of England and Scotland, has inflicted much loss, and caused very damaging inconvenience to graziers, breeders, the cattle trade, and all those concerned in it or with it; and after two months it still remains in the country. Surely it would be far better

Digitized by Google

to dispense with the importation of live animals altogether, seeing that they form but a small fraction of our requirements, and rely only on a dead meat trade. This appears to be the course which it is desirable, both in the name of common sense and humanity, to adopt.

ROYAL MEDICAL BENEVOLENT COLLEGE.

THE annual general meeting of the governors of this institution will be held at the offices, 37, Soho-square, on Thursday, May 26th, when the results of the voting for the election of the pensioners and foundation scholars will be announced. The loss of the late Earl Granville as President of the College makes it necessary for the Council to appoint a successor to that office. It is proposed that the Right Hon. the Earl of Derby shall be elected at the forthcoming meeting of governors. Among the members of the House of Lords are some of the soundest, most intellectual, and earnest friends of education to be found in this country, and conspicuous among them is Lord Derby. He has largely devoted both time and talent on behalf of education. Speaking of Epsom College, the late Lord Granville said that to an educated assembly "nothing could be more grateful and agreeable than the progress of such a school or college which aims at material and intellectual advantage for the sons of medical men." We believe Lord Derby will share the views of his illustrious predecessor. Other business will be the election, as Vice-Presidents of the College, of Dr. Holman, who has for so long acted as treasurer of the institution; of Mr. J. J. Pernell, who has done great service to the institution; and of Mr. Wakley. In accordance with the provisions of the Act of Incorporation, ten members of the Council will retire at the meeting, and it will be proposed that nine of them—viz, Dr. Baines, Dr. Bradley, Dr. De Tatham, Dr. Drage, Sir John R. Jennings, Mr. J. J. Pernell, Sir Edward H. Sieveking, Dr. Waterworth, and Sir Arthur Watson, Bart., Q.C.—be re-elected for a further period of three years, and that Mr. Hugh E. Vardon, be elected to fill the vacant place.

THE SUPPOSED POISONING OF A RACE-HORSE.

MUCH sensation, amounting almost to consternation, has been excited in the horse-racing world for some days by the announcement that Orme, a most promising thoroughbred colt belonging to the Duke of Westminster, had been poisoned at the Kingsclere training stables. The horse had already given proofs of such excellence as a race-horse that he stood in high favour as a probable winner of the great events for which he has been entered. It came, therefore, as a most startling surprise to sporting men, and even to a portion of the public who do not claim to be particularly interested in turf matters or in betting, when it was reported that this favourite *par excellence* had been tampered with by poisoning, and that his chances of running in the important engagements in which, it had been predicted, he was certain to be successful were very small indeed. As usual, all kinds of rumours and surmises were afloat as to the object and mode of poisoning, as well as to the nature of the drug. And the suspicion that the colt had really been poisoned was confirmed by the publication of a reward of £1000 offered by his noble owner for information that would lead to the conviction of the presumed poisoner. Various versions of the case are given, but it would appear that the horse was in good health up to a certain day, when it was observed that there was some salivation and trouble in masticating. The teeth were supposed to be at fault, and a horse dentist was called in, who appears to have attempted to remove one or two teeth, a rather unusual operation, we believe, on a young horse in process of shedding its teeth and growing permanent ones. Afterwards the tongue was found to be swollen, and the veterinary surgeon who was consulted discovered blisters—one account says abscesses—under the tongue. Otherwise there was nothing whatever, it would seem, to show that the health was in any way affected. The blisters or abscesses were lanced, the tongue was soon all right, and the horse seemed to be progressing towards recovery, though later reports are not so satisfactory. From the very incomplete statement of facts which has been made we are not at all in a position to arrive at a definite conclusion, but we are inclined to think it was not a case of poisoning at all, but merely an attack of simple gingivitis or glossitis, to which horses and cattle, no less than human beings, are liable, and that the inflammation was greatly aggravated by the dental troubles. The specially localised lesion, the absence of sloughing or injury to the buccal mucous membrane, and the apparently rapid recovery, do not indicate injury by a corrosive agent. At best it is a mere suspicion, which has but very slight foundation indeed when we take into consideration the above-mentioned circumstances, the great watchfulness exercised by the trainer by night and day, the manner in which the colt is attended to and stabled, and the remote position of the training stables. This, too, seems to be the notion among those best able to judge of the event; and certainly, for the credit of mankind, it is the one we should prefer to entertain until there is more tangible evidence of poisoning. It is indeed most difficult to believe that an irritant poison would be administered to a horse with malicious intent by anyone in the employment of such an acute and careful trainer as he who presides over the establishment at Kingsclere. The drugging of race horses is not unknown, but in such cases it was done immediately before the horses had to compete in a race, and had for its object the rendering the animals merely temporarily unfit to win. So there is reason to hope and believe that the rumoured poisoning of Orme is a false alarm.

MIDWIVES' BILL.

THE following will be nominated as the Select Committee on the Midwives' Registration Bill:—Mr. Bright, Mr. Egerton, Dr. Farquharson, Sir F. Fitz-Wygram, Dr. Fox, Mr. Howorth, Sir G. Hunter, Mr. H. F. Pease, Mr. Rathbone, Mr. Stephens, and Mr. A. J. Williams. A chairman will be immediately appointed and a course of procedure agreed on. But the impending dissolution of Parliament is likely to make any progress towards the settlement of this question very improbable.

THE UNIVERSITY OF LONDON.

AT the meeting of Convocation of the University of London, which will be held on Tuesday next, at 5 P.M., the question of the Gresham University will be raised in the report of the annual committee, and will probably come under discussion during the meeting. The proceedings at the presentation on Wednesday will be exceptionally interesting, as it will be the first occasion on which the Earl of Derby, the present Chancellor, will preside.

THE MYTHOLOGY AND PSYCHOLOGY OF THE ANCIENT EGYPTIANS.

THE paper read at a recent sitting of the Anthropological Society by Mr. Joseph Offord, jun., on the Mythology and Psychology of the Ancient Egyptians was quite *hors ligne* in point of original research, besides showing rare familiarity with the findings of the later—chiefly French—Egyptologists. Every part of it was interesting, especially that devoted to the so-called Book of the Dead. We hope it will be made *publici juris*, confident that its acceptance with the ever increasing circle of readers for whom the early civilisation of the Nile Valley is perennially

Digitized by Google

attractive must encourage Mr. Offord to continue his researches till he has thrown a fuller light than we at present enjoy on the healing art itself as it was professed and practised in the Egyptian foretime. Our standard histories of medicine—German, Italian, and French—are disproportionately meagre and unsatisfactory on this most interesting stage of the subject, and much yet remains to be contributed to our knowledge by investigators like Mr. Offord, whose labours bear the mark of special aptitude, prosecuted as they are in the intervals of other and by no means cognate avocations.

THE MEDICAL SOCIETY'S CONVERSAZIONE.

THE annual conversazione of this ancient Society was held on Monday last. Sir James Crichton-Browne delivered the oration on Sex in Education, a full report of which will be found in another part of our present issue. Afterwards the president held a reception, which was largely attended by the Fellows of the Society and by many distinguished guests. The oration was listened to with marked attention, and at its conclusion the orator received well-merited and marked applause. A vote of thanks to the orator was proposed by Dr. Hare and seconded by Mr. Henry Power. Cigars and refreshments were afterwards provided, and the string band of the Royal Horse Guards played a choice selection of music. The rooms were tastefully decorated with flowers and palms, and the electric light added much to the beauty of the effect, and the evening seemed to be well enjoyed by the large number of Fellows and guests who assembled. This method of happily terminating a session of useful work we heartily commend for imitation by the sister Societies.

THE ROYAL COMMISSION ON VACCINATION.

THE delay which occurs in the publication of the interim report of the Royal Commission on Vaccination is doubtless due to the method of procedure which has to be adopted. All reports of Royal Commissions have to be submitted by a Secretary of State to Her Majesty, and only after this has been done can they be laid before Parliament or made public. The Queen's journeys may in this case have added to the difficulty of complying with this invariable rule.

DIFFERENTIAL PULSE IN CERTAIN HEART AFFECTIONS.

PROFESSOR L. V. POPOFF, writing in the *Meditsinskoĭ Obozrênie* on the cause of a difference in the radial pulse on the two sides in certain heart affections, says that this phenomenon is frequently observed with mitral stenosis, associated with mitral incompetence, especially where there is considerable disturbance of the compensation, the pulse being small and irregular, and the dilatation of the heart, and especially of the left ventricle, very marked. Under these conditions the pulse in the left radial artery is found to be decidedly weaker than that in the right—sometimes, indeed, the latter may be easily counted while the former is scarcely perceptible. Sometimes the pulse is so small and weak that it will not give a sphygmographic tracing, and the difference can only be detected by the feel. As the heart's action improves the difference gradually becomes less and less marked. In explanation of this, Professor Popoff states that he found in these cases that there was a pressure of the enlarged auricle and its appendix, and even of enlarged pulmonary vessels, against the arch of the aorta, and especially against the part from which the left subclavian arises. Of course, if the heart's action is feeble such a pressure must diminish the circulation through the left arm in comparison with that through the right; but if the aorta is well filled out, this pressure may have but little effect. Again, probably the greater length of the arterial course on the left side, and the more acute angle which the left subclavian makes with the arch of the aorta as compared with that made by the right subclavian with the innominate, must be borne in mind, as it has probably some influence on the question. The differential pulse is more frequently observed in young or middle-aged subjects than in elderly people, as in the latter the heart, owing to the loss of elasticity and consequent elongation of the great vessels, lies lower, and therefore further away from the arch of the aorta.

HYDROCHLORIC ACID IN THE TREATMENT OF VOMITING

DR. ALKIEWICZ, writing in the *Nowiny Lekarskie*, mentions that in various kinds of vomiting he has found great benefit from small and frequent doses of hydrochloric acid, well diluted of course. In one case of the vomiting of pregnancy, where none of the ordinary remedies had any effect, hydrochloric acid proved successful, though it had to be given for a fortnight before it entirely arrested the sickness. In more than ten cases of cholera nostras in adults, with vomiting, hydrochloric acid was given with good results. Again, where vomiting was due to acute dyspepsia from errors in diet, and where it occurred in the course of influenza, scarlet fever, or other contagious diseases, the same remedy proved equally efficacious.

THE DISCIPLINARY POWERS OF THE ROYAL COLLEGE OF SURGEONS, EDINBURGH.

A CASE of some interest has been before the Calcutta High Court of Justice. Mr. Laurence Fernandez, M.D., and Licentiate of the Royal College of Surgeons of Edinburgh, carried on business in an institution known as the "Medical Hall," otherwise a chemist's shop. He advertised freely and sold drugs over the counter. We learn from the local press that for such practices he received a communication from the College of Surgeons of Edinburgh, informing him that the College considered his business catalogue highly objectionable and unprofessional, and unless it were withdrawn it would be necessary to consider whether his name should not be struck off the list. In reply, Mr. Fernandez wrote that he would discontinue the catalogue and cease his connexion with the firm. He then appears to have assigned his lease and his interest in the business to his mother (who transferred it to another son), came to Europe, and obtained the Brussels degree. He then went back, declared the deed of transfer only a bogus one, commenced a suit to recover possession, and succeeded. What will the Edinburgh College do now, to say nothing of the University of Brussels?

THE ACTION OF ANTIPYRIN ON THE BACILLUS OF DIPHTHERIA.

M. VIANNA of Bahia, in Brazil, has been investigating the action of antipyrin upon Löffler's bacillus, and finds that it has marked bactericidal powers upon the pathogenic organism of diphtheria, and also that it destroys the toxic properties possessed by the products of that microbe. His results are published in *Le Bulletin Médical*, March 30th, 1892. In his first series of experiments, M. Vianna found that in the proportion of 2½ per cent. antipyrin prevents the development of the bacillus of diphtheria in the various culture media in which it will usually grow. More than this, the addition of antipyrin to the tubes containing Löffler's bacilli in full growth killed them in less than forty-eight hours. The same result is attained in twenty-four hours, when the proportion of antipyrin is raised to 5 per cent. If the same proportions of the drug as those given above are added to the bouillon filtered from the bacillus, which will contain the toxic substances

Digitized by Google

(which have been so fully investigated by Dr. Sidney Martin, and described by him in the Goulstonian Lectures) elaborated by it, it may be proved that the poisonous products of the micro-organisms lose in part these toxic properties. For instance, guinea-pigs were inoculated with the filtered bouillon from cultures of the bacillus of diphtheria, and all died in less than three days; whilst if from 4 to 8 per cent. of antipyrin were added, the animals lived from five to twenty-four days, thus showing that although the drug did not render the inoculation harmless, yet its toxicity was considerably diminished.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—Dr. Köhler, of the Friederich Wilhelm's Institute, for many years assistant in Professor von Bardleben's clinic, has been granted the title of Professor.

Dorpat.—Professor Heinrich Unverricht has been offered charge of the new hospital at Magdeburg.

Freiburg.—Dr. Gustav Killian, *privat-docent* in Laryngology and Otology, has been appointed Extraordinary Professor. Dr. Wesener, of the Policlinic, has also been appointed Extraordinary Professor of Medicine.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Karl Fromman, Extraordinary Professor of Histology in the University of Jena, whose chief work was on the Structure of the Ear and of the Central Nervous System, at the age of sixty-one. He resided for a time in England some thirty years ago.—Dr. H. Girard, *privat-docent* in Physiology in the University of Geneva.

SIR RICHARD QUAIN was entertained at dinner last week at the Garrick Club by a select company, including Mr. David Plunket, Mr. Irving, Mr. Toole, Sir Charles Russell, Mr. Edward Lawson, Mr. J. Hare, Mr. Beerbohm Tree, Mr. Comyns Carr, Mr. Pinero, Mr. A. Levy, Mr. Clement Scott, Mr. F. H. Maclean, and Mr. C. W. Mathews. Mr. Hare presented him, as a souvenir of their sincere regard, with two antique silver bowls engraved with the names of the donors.

PROFESSOR GEORGE HARE PHILIPSON, M.A., M.D., D.C.L., F.R.C.P., has been elected the representative of the University of Durham on the General Council of Medical Education and Registration of the United Kingdom.

PROFESSOR CLIFFORD ALLBUTT, the Regius Professor of Physic in Cambridge University, proposes to give his inaugural lecture on Tuesday, May 10th, at noon, in the new Anatomical Theatre.

THE inquiry into the question of fresh legislation on the subject of habitual drunkenness is, we understand, to be a departmental one.

THE ROYAL SOCIETY CONVERSAZIONE.

IT is meet that the Society which represents science should hold its first annual conversazione a few days after the opening of the Royal Academy in the adjoining rooms at Burlington House. Just as the one exhibition marks the progress made in art during the past year, so may the annual conversazione of the Royal Society be taken to indicate the advances made in science. Lord Kelvin received a number of Fellows and distinguished visitors at the conversazione held on Wednesday last, and the variety of subjects exhibited must have afforded interest to all grades of scientific workers. Electricity attracted, perhaps—as it has done in previous years—the lion's share of interest. The very remarkable phenomena exhibited by electric currents of high potential and extreme frequency recently investigated and ably demonstrated by M. Tesla formed the subject of Professor Crookes' beautiful demonstration. Professor Crookes, who is well known for his admirable researches on a related subject, explained that in these experiments the discharges from a battery of Leyden jars are sent through the primary wire of an oil induction coil. The wave length of the jar radiation is 300 metres, the frequency of alternation is 1,000,000 a second, and the electro-motive force about 100,000 volts. Stream and brush discharge, luminous conducting wires, phosphorescence of air, oxygen, yttria, sulphide of calcium, diamonds, rubies, &c., were amongst the most noteworthy phenomena of the secondary poles. Odd as it may seem, the physiological action of the high frequency current is feeble, although the shock of the force in its initial condition would probably kill instantly. An electric chronograph, designed for recording the velocity of projectiles and small periods of time in physiological research, was the ingenious invention of the Rev. F. J. Smith. Professor Oliver Lodge strikingly illustrated lightning effects and multiple flashes by the passage of sparks in and to water. A spark to water spreads out on the surface in a crow-foot pattern, showing apparently that the surface layer is a feeble dielectric. A spark under water is short and very violent, treating the water as a dielectric and producing concussion. Vacuum tubes without electrodes was the subject of Dr. Bottomley's exhibit. These tubes show all the beautiful phenomena of stratification, and also the phenomena accompanying the "sensitive state," though they have no electrodes. They show also the phenomena of molecular bombardment. The lecture-room apparatus exhibited by Professor Thorpe, and described recently in THE LANCET, is intended to demonstrate the general phenomena of a dust explosion, and more particularly coal dust, in explanation of the causes of colliery explosions. Touching the same subject, Professor Clowes showed an ordinary miner's safety-lamp, with supplemental hydrogen flame, for detecting and measuring minute proportions of firedamp or inflammable gas or vapour in air. An ordinary oil or benzoline safety-lamp is fed with hydrogen by a tube passing through the oil reservoir, and connected when necessary by a flexible tube with a light steel bottle containing compressed hydrogen. The hydrogen becomes kindled by the lamp flame, which is then extinguished by drawing down the wick. The hydrogen flame is adjusted to a standard height, and the amount of inflammable gas or vapour is estimated by the dimensions and appearance of the "cap" which is seen over the flame. Percentages of firedamp varying from 0·25 to 3 could thus be detected and estimated, and the luminous flame of the lamp alone, when sufficiently reduced, serves to detect percentages above 3. Specimens were shown by Professor Church illustrating the occurrence and properties of turacin, the red pigment (containing 7 per cent. of copper) discovered by the exhibitor in the wing feathers of certain plantain eaters or touracos. Dr. MacMunn exhibited the spectra of this interesting pigment. It is remarkable for its spectrum, which closely resembles that of oxy-hæmoglobin. Its derivatives have recently been found to give spectra closely resembling those of the derivatives of hæmoglobin. The demonstration of Mr. Frederic E. Ives of Philadelphia on composite heliochromy, a process of colour photography, was listened to with intense interest. The effects on the screen were very beautiful and wonderfully realistic, so that it was difficult to imagine that one was looking at a photograph at all. A geranium in bloom, in an ordinary flower-pot, and a little girl in a coloured frock surrounded by trees in full leaf, were particularly striking subjects, all the colours being portrayed with remarkable faithfulness. Professor Boys showed his photographs of flying bullets. The photograph of an aluminium bullet from a magazine rifle and smokeless powder, projected at the enormous velocity of 3000 ft. per second, was the centre of interest. Chemists have long struggled to produce certain gems artificially and with partial success; but it has been left to Mr. W. Saville Kent, a Fellow of the Linnæan Society, to induce and to accelerate the formation of pearl. He exhibited a pearl artificially produced through an operation performed by the exhibitor on the living animal.

Space prevents us giving more than passing mention to many other exhibits of equal interest. Such were, for

Digitized by Google

example, Professor Norman Lockyer's photographs of the new star and the Solar Physics Committee's photograph of the great sun-spot of February last, the optical pyrometer of Professor W. C. Roberts Austen, and, lastly, certain new and rare fish, some new to British and Irish waters and one altogether new to science, exhibited by Professor A. C. Haddon and Mr. E. W. L. Holt.

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE Committee of the Association of Fellows of the Royal College of Surgeons met at 5 P.M. on April 26th, at 36, Grosvenor-street. In the unavoidable absence of the President, Mr. George Pollock, Mr. T. Holmes, the senior Vice-President, occupied the chair. The honorary secretary, Mr. H. Percy Dunn, read a letter from the secretary of the College, in answer to a letter sent by the committee to the President of the College, conveying the following resolution passed at the last meeting: "That the committee of this Association, having noticed that the Council of the College has appointed a committee to consider the claims of the Fellows, would suggest that a deputation from the Association of Fellows should be asked to meet the committee in order to set forth the views of the Association." The following was the secretary's reply:—

Royal College of Surgeons, Lincoln's inn-fields,
London, W.C., April 25th, 1892.

DEAR SIR,—I am desired by the President to acknowledge the receipt of your letter of the 23rd instant, and to acquaint you that the same will be submitted by him to the Council at their meeting on the 12th proximo. The President is not aware that any committee has been appointed by the Council to consider the claims of the Fellows, "but presumes it to be the intention of those who framed the resolution reported in your letter to refer to a committee appointed by the Council on the 10th of March last to consider and report to the Council whether any, and if so what, further advantages can be extended to the Fellows."

I am, dear Sir, yours faithfully,
H. Percy Dunn, Esq. EDWARD TRIMMER, Secretary.

The difference between the two descriptions of the objects of the committee is more apparent than real. As long ago as the end of October, 1890, the Committee of the Association of Fellows sent a deputation to meet a Committee of the Council of the College, in order to urge upon them certain claims on behalf of the Fellows of the College. These claims were on the whole favourably received by the committee, but the consideration of the most important of them was deferred by the Council, in deference to legal advice, until the decision of the action Steele *v.* Savory. As soon as that action had been settled, a committee was applied for in the Council of the College, for the purpose of redeeming the implied pledge to the Committee of the Association to consider their propositions at the earliest opportunity. Of course, under the terms of the reference to the committee, other points can be considered besides those urged by the Committee of the Association of Fellows, and therefore the expression used in the letter of the honorary secretary of the Association may be regarded as too narrow. We are inclined to believe, however, that the object of the correction in the letter of the secretary of the College was rather to narrow the expression used by the honorary secretary of the Association than to enlarge it. The Council of the College is the fountain of grace and favour, and any advantages which may possibly be extended to the Fellows must rise spontaneously from this source and flow down to the Fellows, who can only be worthy to receive them if they have a becoming sense of the gracious condescension of the Council of the College. Unfortunately the spring often runs dry, and is rarely available except during the rainy season and disturbance of the elements, and it is the business of the Association of Fellows to prevent the too lengthened continuance of the period of drought. In the present instance the committee of the Association wisely decided that the mere verbal amendment of the secretary's letter did not call for any notice.

The main business of the committee was to consider a report of the proceedings of the Association of Fellows since March, 1890, when the first report was issued. The report had been drawn up by Mr. Rivington and Mr. Percy Dunn in the first instance and submitted to and approved by a subcommittee. After the report had been read and briefly discussed, it was resolved: "That the subcommittee be instructed (1) to complete and, where practicable, to abbreviate the report; (2) to have the report printed so as to enable each Fellow of the College to have a copy transmitted to him during the second week in June; (3) to insert a slip in the printed report asking (*a*) those who approve of the objects of the Association to notify the same to the honorary secretary, and to become members; (*b*) to support the candidates adopted by the Association for election into the Council."

The date of the annual meeting of the Association was fixed for Thursday, June 23rd, at 5 P.M., and the honorary secretary was instructed to write to the Council of the Royal Medical and Chirurgical Society requesting permission to hold the meetings in question in the rooms of the Society. It was also decided that the annual dinner of the Association should be held in the evening of the day of the annual meeting.

On April 2nd we announced that the Committee of the Association of Fellows had unanimously resolved to ask Mr. Tweedy to allow his name to be put forward as the candidate of the Association at the next annual election to the Council of the College. Mr. Tweedy now stated, in reply to that request, that he had decided, after due consideration, to accept the invitation of the committee, and if elected he would do his best to advance those constitutional interests of the Fellows for which the Association had been so long contending. He would much have preferred the selection of some other candidate; but as his colleagues on the committee desired it he was willing to stand. The number of seats to be filled at the ensuing election will be four, owing to the decease of Mr. Berkeley Hill and the approaching retirement of Messrs. Smith, Durham, and Lawson. Of these gentlemen, Mr. Lawson has decided not to be again nominated, so that there will be at least two absolute vacancies. In view of this fact, and of the intention of Mr. Lawson Tait, expressed at the last meeting of the committee, to come forward again, it was proposed by Dr. Collins, seconded by Mr. W. Barnes, and carried *nem. con.*: "That Mr. Lawson Tait be asked to stand as a candidate of the Association at the College election in July next." Mr. Tait has now fought the battle of reform under the auspices of the Association for three successive years, and has always polled a large number of votes—more, in fact, than some successful candidates have received in other years, and it is to be hoped that both Mr. Tweedy and Mr. Tait will be successful this year. Their election would so strengthen the growing reform party in the Council as to ensure the realisation of all the changes which have been asked for by the thinking portion of the constituency of Fellows.

THE INTERNATIONAL CONGRESS OF THE RED CROSS.

THE sitting of the 25th ult. was occupied with important business. After the Commission charged to study the question as to how far the Red Cross societies could intervene in distant wars had been nominated, a discussion arose on the demand of M. Oom (representing Russia) that Customs House examinations and dues should be suspended in favour of the *matériel* of the Red Cross, and also that the *personnel* of the societies should be conveyed by the railways free of cost. The Marchese Vitelleschi contended that so far as Italy was concerned her customs houses have relaxed their rules in the case of Red Cross goods, and also that her railways contemplate the conveyance of the *personnel* at reduced fares. M. Ziegler (Switzerland) maintained that the exemption from Customs dues was too large a question for the Red Cross Congress to decide *per se*, and that the Swiss railways, belonging as they did to private companies, could be used gratuitously by the *personnel* only after the consent of the companies had been obtained. The discussion closed with an approval of the demands formulated in the name of Russia by M. Oom.

The next discussion turned on the question as to the intervention of the Red Cross at military manœuvres in time of peace, with a view to disciplining its *personnel* and testing its resources, so as to avoid the *contretemps* it ex-

Digitized by Google

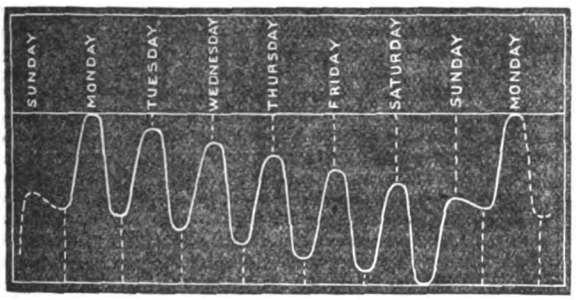
perienced in the late wars. The affirmative side was maintained by the Hungarian delegates, the negative by the German, French, Dutch, and (in part) by the Italian. Herr Criegern (Saxony) held that in Germany the Red Cross will never be made to serve in the first line—that is, in the field of battle; it will be called into activity only after the battle is at an end. Herr Kuesebeck (Germany) supported this affirmation, and added that at the German manœuvres, to avoid grave embarrassment to the military authorities, not even the Army Medical Service was allowed to intervene. Eventually the following motion was introduced and carried: "The Fifth International Congress expresses the desire that a commission should endeavour to ascertain in what measure the Red Cross Societies may be put in a position to profit by the autumn manœuvres for the instruction of their *personnel*."

Other resolutions relating to the discipline of the *personnel* came up, the most important of which, as tabulated by Herr Kuesebeck, were approved. These last ran as follows: "1. It is among the principal duties of the Red Cross Societies to prepare a numerous body of attendants on the wounded which shall be as well trained and efficient as possible. 2. This duty resolves itself into two parts: (*a*) instruction of a *personnel* having the qualities, moral and physical, required for hospital service; (*b*) instruction of the said *personnel* having similar qualifications for the transport of the wounded. 3. The hospital instruction shall comprise also the principal functions of transport of the wounded. 4. The examination of the results obtained shall rest with the military authorities. 5 And lastly, it is desirable to enhance the utility of the *personnel* of the organisations created *ad hoc* even in time of peace."

On the 26th the following proposal of M. De Martens (Russia) was, after an animated discussion, approved:—"Considering that the perfecting of lethal arms progresses every day, considering that the number of victims in future wars will certainly increase, the Fifth International Congress of the Red Cross recommends to the earnest consideration of all the associations the absolute necessity of profiting by every means possible, so as to diffuse the propaganda of the Red Cross in all classes of the populations, and to augment the resources required not only to mitigate the horrors of war, but also to alleviate public calamities." In this connexion M. De Martens pointed out the signal service rendered by the Russian associations of the Red Cross in the recent famine, in which they distributed relief to the amount of twenty-five million francs. After this the Congress proceeded to discuss the conditions of the open competition for perfecting the means of transporting, with efficacy and promptitude, the wounded from the battlefield to the first line of relief stations and thence to the temporary hospitals. Signor Tosi (Italy) and M. Leurs (Belgium) proposed that the competitors should present a typical model of the means they suggest, on the scale of one-fourth the real size, with relative descriptive matter; and that both model and description should be on view in Rome from Aug. 15th to Sept. 15th, 1893, having been sent in to the adjudicating committee before June 30th of the same year. This proposal was approved. Further discussions took place on the "Sterilisation of the *matériel* of medication;" on the employment of the fund placed at the disposal of the Red Cross by the Empress Augusta; and on the propriety of introducing electric lighting for the nocturnal service of the Red Cross in removing the wounded from the battlefield; after which came up for reconsideration the intervention of the Red Cross in distant wars. Objections having been heard and dealt with, the conclusions of the majority of the commission were sustained, it being generally admitted that the military authorities of the belligerent powers will be in the best position to remove whatever inconveniences may arise from the operations of the Red Cross service on either side.

On the 27th (the last sitting of the Congress) M. Santos Ferreira (Portuguese delegate) proposed that "all the associations for relieving the wounded in war in relation with the international committee of Geneva should, in their rubric, assume the name of the Red Cross." This evoked some demur on the part of the French delegates; but, after a good deal of discussion, the following amendment, introduced by M. Odier (Switzerland), was carried: "That, in the countries where, under authorisation of the Government, more than one society exists with the name and object of the Red Cross, these societies may arrive at a fusion or federation which may admit of their entering the groups of all the national societies represented at the International Congresses." Reverting to a discussion of the previous day on the task of the Red Cross in view of the increasing efficacy of lethal arms and instruments of destruction—particularly as to explosives—M. Socin (Switzerland) indicated how the duty of the associations would become at once more difficult and more imperative. He concluded an interesting speech by moving the following resolution: "The fifth Congress renders full justice to the ideas inspiring the proposal of MM. Mundy, Socin, Furley, De Thomsen, and De Montagnac, that the associations should take special account in their preparations of the effects of the new arms and projectiles of warfare; but that, not believing itself sufficiently competent at this stage for the special treatment of the question, the Congress remits it to the consideration of all the central committees, and proposes that these should combine at the next general Congress in a report embodying their unanimous conclusions." This was approved, after which, on the motion of M. Leurs (Belginm), it was agreed to confide to the Geneva committee, in accord with the other central committees, the task of fixing the seat of the next (the sixth) International Congress. This also was carried, and the President, Count della Somaglia, wound up the proceedings in a felicitous address. "Let me conclude," he said, "by expressing a wish very near my heart that the banner which I see in the midst of us may ever wave in this atmosphere of friendship and concord, and that our association of the Red Cross shall henceforth be nothing more than a brotherly reunion of unemployed (*disoccupati*)!" Compliments and congratulations between the delegates of the powers represented ensued, after which the Minister of War (Signor Pelloux) declared the Congress closed.

By universal admission this has been from first to last a most effective and harmonious gathering, fraught with important results which will make themselves felt in a long series of its successors. Its accessory features were also of the most gratifying description. Nothing could have been more brilliant than the royal banquet at the Quirinal Palace, unless, perhaps, the joyous excursion to Tivoli, where a highly satisfactory demonstration of a mountain ambulance in working was followed at the Villa d'Este by a great symposium, made memorable not only by the matchless beauty of the surroundings, but by the truly fraternal spirit which inspired the representatives of so many and such diverse nationalities.



THE PHYSIOLOGY OF LABOUR.

IN view of the recent May Day demonstration in support of "an eight hours day," it may be interesting to recall the experiments by which Pettenkofer and Voit attempted to ascertain what amount of work a healthy labourer could accomplish without injury to his health. They constructed a chamber in glass which was hermetically closed. Inside they placed a wheel to which was attached a chain. By turning the wheel the chain raised a weight of 25 kilogrammes. A healthy vigorous labourer was put inside this glass room; and, deducting the time required for meals, he was made to turn the wheel for nine hours a day. This was considered equivalent to hard physical work. The workman was carefully weighed before and after the experiment, the food supplied to him was likewise weighed and analysed. Very great care was taken to make this glass room absolutely air tight. No air could get in or out excepting through the air inlet and the air outlet. Thus it was possible to analyse the air as it went in and as it came out. Pettenkofer was therefore able to ascertain that during the nine hours' work the labourer had expended in the form of carbonic acid 192 grammes of oxygen more than he had been able to inhale during that time. To cover this deficit, it was calculated that the workman must have expended 20 per cent. of the provision of oxygen stored in his system. Of course this deficit was to some extent compensated by the night's repose; but, nevertheless, the balance was not re-established. During the night he naturally absorbed more oxygen than he utilised. But as the respiratory organs work more slowly at night the process of recuperation was not sufficiently prolonged. Both Pettenkofer and Voit came to the con-

Digitized by Google

clusion that a night's rest was not sufficient to re-establish the normal condition after a day of very fatiguing toil. They were of opinion that the deficit might be equal to 10 per cent., and in some cases 20 per cent., of the total stock of energy, and this in spite of the restorative effect of a good night's rest. It was the Sunday rest that alone could enable the body to take up the oxygen lost during the week's toil. Dr. Hoegler of Bâle published on this question a diagram showing the daily loss and gain throughout the week. It will be noticed how the line dips

Dr. Hoegler's diagram, showing the recuperative effect of weekly rest.

The top of the wave represents the vitality acquired after the night's rest, and the bottom of the line the vitality lost after the day's work.

down for the working hours of the day and rises again at night, but it does not reach its starting point, so that by Saturday the line is very low indeed. On Saturday night it reascends to a point a little below the level of Friday night. But on Sunday, as it hardly descends at all, a similar rise on Sunday night brings it up to about the same level as that at which the start was made on the previous Monday. These experiments, though extremely interesting and suggestive, must only be taken as an approximate indication of the effects of hard work. Where the atmosphere is vitiated by gas, poisonous dust, insufficient ventilation, the results must be much worse than those found in the sort of model existence led by the workman who was imprisoned in a glass room by Professor Pettenkofer. On the other hand, perhaps the workman in the glass room did more muscular work than others who toil in unwholesome factories or workshops. What can, however, be said without fear of contradiction, is that there is a distinct limit to the human power of physical endurance, and that this limit can be exceeded in nine hours' work, though performed by a thoroughly healthy worker. Therefore, Pettenkofer's experiments would lead us to conclude that eight hours' hard muscular work is quite as much as may be safely undertaken even by the strong and healthy.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6547 births and 4057 deaths were registered during the week ending April 30th. The annual rate of mortality in these towns, which had been 20·9 and 21·8 per 1000 in the preceding two weeks, declined again last week to 20·8. In London the rate was 19·8 per 1000, while it averaged 21·5 in the thirty-two provincial towns. The lowest rates in these towns were 9·9 in Brighton, 10·8 in Croydon, 11·8 in Portsmouth, and 15·5 in Nottingham; the highest rates were 24·9 in Birmingham, 26·3 in Manchester, 27·3 in Birkenhead, and 27·5 in Liverpool. The 4057 deaths included 527 which were referred to the principal zymotic diseases, against numbers increasing from 428 to 541 in the preceding four weeks; of these, 242 resulted from measles, 154 from whooping-cough, 41 from scarlet fever, 36 from diarrhœa, 33 from diphtheria, 18 from "fever" (principally enteric), and 3 from small-pox. No fatal case of any of these diseases occurred last week in Croydon or in Plymouth; in the other towns they caused the lowest rates in Brighton, Norwich, Wolverhampton, and Gateshead, and the highest rates in Birkenhead, Liverpool, Preston, and Sunderland. The greatest mortality from measles occurred in Manchester, Sheffield, London, Birmingham, Liverpool, Birkenhead, and Leicester; from scarlet fever in Cardiff; from whooping-cough in Derby, Hull, Preston, Salford, and Sunderland; and from diarrhœa in Burnley. The mortality from "fever" showed no marked excess in any of the thirty-three large towns. The 33 deaths from diphtheria included 17 in London, 3 in Portsmouth, and 2 each in West Ham, Birmingham, Liverpool, and Manchester. Two fatal cases of small-pox were registered in London, and one in Liverpool, but not one in any other of the thirty-three towns; 49 cases of this disease were under treatment in the Metropolitan Asylum Hospitals, and 12 in the Highgate Small-pox Hospital, on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1408, against 1296 and 1400 on the preceding two Saturdays; 177 new cases were admitted during the week, against 146 and 219 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 348 and 389 in the preceding two weeks, declined to 306 last week, and were 78 below the corrected average. The causes of 77, or 1·9 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bradford, Sunderland, Newcastle-upon-Tyne, and in six other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined from 24·1 to 22·3 per 1000 in the preceding three weeks, further fell to 21·3 during the week ending April 30th, but exceeded by 0·5 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·4 in Leith and 15·5 in Perth to 21·4 in Edinburgh and 23·8 in Glasgow. The 593 deaths in these towns included 26 which were referred to whooping-cough, 18 to measles, 14 to diarrhœa, 4 to scarlet fever, 4 to diphtheria, 4 to "fever," and not one to small-pox. In all, 70 deaths resulted from these principal zymotic diseases, against 73 and 63 in the preceding two weeks. These 70 deaths were equal to an annual rate of 2·5 per 1000, which was slightly below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had declined from 30 to 22 in the preceding three weeks, increased to 26 last week, of which 16 occurred in Glasgow and 4 in Paisley. The deaths referred to measles, which had been 18 and 15 in the previous three weeks, rose again to 18 last week, of which 17 occurred in Glasgow. The 14 fatal cases of diarrhœa were within 3 of the high number in the preceding week, and included 9 in Glasgow. The deaths from diphtheria, which had been 10 and 6 in the previous two weeks, further declined to 4 last week, of which 2 occurred in Glasgow, where 3 of the 4 fatal cases of scarlet fever were also recorded. The deaths referred to diseases of the respiratory organs in these towns, which had been 130 and 163 in the preceding two weeks, declined again last week to 139, and were 7 below the number in the corresponding week of last year. The causes of 47, or nearly 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 30·6 and 35·8 per 1000 in the preceding two weeks, further rose to 43·9 during the week ending April 30th. During the first four weeks of the current quarter the death-rate in the city averaged 35·8 per 1000, the rate for the same period being 20·6 in London and 20·1 in Edinburgh. The 294 deaths in Dublin during the week under notice showed an increase of 54 upon the number in the preceding week, and included 20 which were referred to measles, 11 to whooping-cough, 1 to diphtheria, 1 to "fever," 1 to diarrhœa, and not one either to small-pox or scarlet fever. In all, 34 deaths resulted from these principal zymotic diseases, equal to an annual rate of 5·1 per 1000, the zymotic death-rate during the same period being 3·3 in London and 21·5 in Edinburgh. The fatal cases of measles, which had

Digitized by Google

been 14 and 33 in the preceding two weeks, declined again to 20 last week. The deaths referred to whooping-cough, which had increased in the previous three weeks from 3 to 10, further rose to 11 last week. One fatal case of "fever" was recorded during the week under notice, against 6 and 1 in the previous two weeks. The 294 deaths registered in Dublin last week included 26 of infants under one year of age, and 79 of persons aged upwards of sixty years; the deaths of infants showed a decline, while those of elderly persons considerably exceeded the number recorded in any recent week. Six inquest cases and 7 deaths from violence were registered; and as many as 123, or more than 40 per cent., of the deaths occurred in public institutions. The causes of 15, or more than 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

THE PROPOSALS OF LORD WANTAGE'S COMMITTEE.

A PARLIAMENTARY paper has been issued from the War Office showing the estimated cost to the United Kingdom and to India of carrying out the recommendations of the Committee on Terms and Conditions of Service in the Army. Without going into the subject of the total estimated cost of all the proposals, which amounts to a large sum, we may say that to free the soldier from compulsory stoppages not due to negligence or misconduct—e.g., hospital stoppages, barrack damages, tailors' and shoemakers' bills, and taking these as amounting on an average to ½d. a day, the extra cost on present establishments would be about—British, £142,000; Indian, £75,000. Giving each soldier throughout the Army 3d. a day as messing allowance, the extra cost on present establishments would be—British, £667,200; Indian, £319,000. There seems to be no doubt that the present condition of the Army, as set forth in the voluminous evidence published in connexion with the Report of Lord Wantage's Committee, will be the subject of a sharp debate later on. There does not appear to be any general disinclination to amend and improve the condition of the rank and file provided it can be done by a saving effected in the expenditure in other directions, such as a reduction in the numbers of the higher ranks. We are glad to notice that Dr. Farquharson has called the attention of the Secretary for War to the condition of St. George's Barracks and the absence of proper provision for the examination of recruits. The inconvenience and discomfort of the place can only have a deterrent effect on recruiting.

It may interest officers of the Army Medical Staff engaged in the medical inspection of recruits to know that a Royal Warrant has been issued providing for civilians acting as recruiting agents, and giving them the same awards as are granted for military recruiters.

Deputy-Inspector-General of Hospitals and Fleets, James Lilburne, R.N., M.D., F.R.C.S. Ed., died on the 23rd ult., at Duncrievie House, Glenfarg, Perthshire.

Surgeon-Colonel Allan, Medical Staff, has been appointed to the Administrative Charge of the Rawalpindi District.

INDIAN MEDICAL SERVICE. — Surgeon-Lieutenant-Colonel Lethbridge's (C.S.I.) services have been placed at the disposal of the Government of India. This officer has been acting upwards of fourteen years as Inspector-General of Gaols, and has introduced great improvements in gaol administration. The Lieutenant-Governor, in an official notification published in the *Calcutta Gazette*, expresses the appreciation in which the merits and services of this officer are held.

The pitiable condition of the native followers of the army in connexion with the late operations in Burma has very properly been the subject of recent comment, *apropos* of some statements in an address given by Deputy-Surgeon-Colonel Sibthorpe, Indian Medical Service. It is alleged that out of nearly 6000 sick followers only 400 recovered sufficiently to return to their duties in the field. As everyone knows, these nations are of essential use in Indian warfare. They are usually very hard worked, badly fed, and insufficiently clad, and occasionally they escape medical inspection altogether, or insufficient care is bestowed in rejecting those unfitted for work in the field. The hardship and suffering these unfortunate people undergo during a campaign entitle them to every consideration. It is to be hoped that the Indian Government will take some steps to guard in future against any similar amount of sickness and loss of life.

ARMY MEDICAL STAFF. — Surgeon-Captain H. R. O. Cross, from the Grenadier Guards, to be Surgeon-Major, in succession to Brigade-Surgeon-Lieutenant-Colonel A. B. R. Myers, retired (dated May 4th, 1892). — Surgeon-Major George Blake Hickson retires from the Service, receiving a gratuity (dated May 4th, 1892).— Surgeon-Captain R. S. F. Henderson has been ordered to Woolwich for duty; Surgeon-Captain G. Wade has been posted to Devonport; Surgeon-Colonel W. Collis has been transferred from Cork to Dublin; Surgeon-Lieutenant-Colonel J. G. Williamson, from Singapore to Gosport; Surgeon-Lieutenant-Colonel R. Drury, from Curragh to Dublin; Surgeon-Majors T. J. Gallwey, Hounslow to Egyptian Army; C. K. Powell, Madras to Cork; R. T. Beamish, Bengal to Dublin; T. M. Corker, Cork to Bombay; S. J. Flood, Belfast to Sierra Leone; J. G. Harwood, Portsmouth to Bengal; Surgeon-Captains T. Archer, Dover to Bermuda; R. C. Johnston, Bengal to Chatham; S. H. Creagh, Aldershot to Bermuda; J. R. Stuart, Warley to Hong-Kong; H. J. Wyatt, Dublin to Bombay; J. R. Mallins, Home District to Bengal; S. Powell, Bengal to Grenadier Guards; R. G. Thompson, Bombay to Sheerness; R. H. Hall, Bombay to Colchester; P. B. Skerrett, Bengal to Castlebar; J. J. C. Watson, Singapore to Aldershot; H. E. H. Smith, Singapore to Portsmouth.—Surgeon-Major J. E. Nicholson, who sailed on the 14th ult. for Hong-Kong in the P. and O. ss. *Oriental*, was entertained by the Principal Medical Officer, Devonport, and his brother officers at a farewell dinner given in his honour at the Royal Hotel, Plymouth.— Surgeon-Captain M. L. Hearn, doing duty in the Secunderabad District, has been posted to the Station Hospital, Bangalore; Surgeon-Colonel F. W. Wade has been placed on the Administrative Medical Staff of the Bengal Army.

MILITIA MEDICAL STAFF.—Surgeon-Lieutenant-Colonel J. E. Thornburn, 3rd Battalion, the Border Regiment, resigns his commission; he is also permitted to retain his rank, and to wear the prescribed uniform on his retirement (dated May 4th, 1892).

YEOMANRY CAVALRY.—Royal 1st Devon: Surgeon-Lieutenant F. Morgan to be Surgeon-Captain (dated May 4th, 1892).

NAVAL MEDICAL SERVICE.—Staff Surgeons: Arthur W. May to the Royal Marine Depôt, Walmer, and William M. Lory to the *Volage* (dated April 29th, 1892); Surgeon Geo. Edmonds to the *Abyssinia* (dated June 1st, 1892).

VOLUNTEER CORPS.—*Rifle:* William George Creswell, Gent., to be Surgeon-Lieutenant (dated May 4th, 1892).— 2nd Volunteer Battalion, the Worcestershire Regiment: Surgeon-Captain T. E. Underhill to be Surgeon-Major (dated May 4th, 1892) —1st Volunteer Battalion, the East Lancashire Regiment: John Michael Harding Martin, M.D., to be Surgeon-Lieutenant (dated May 4th, 1892).— 13th Middlesex (Queen's Westminster): Surgeon-Captain H. A. Des Vœux resigns his commission (dated May 4th, 1892).

INFANTRY VOLUNTEER BRIGADE. — East Yorkshire Brigade: Surgeon-Major J. Blackburne, 2nd Volunteer Battalion, the York and Lancaster Regiment, to be Brigade-Surgeon-Lieutenant-Colonel (dated May 4th, 1892).

FUNERAL REFORM.—As an indication of the increasing attention paid to matters of funeral reform, it is satisfactory to note that at the obsequies of Sir James Allport the mourners, by special request of the deceased, did not uncover their heads beside the grave.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The next quarterly meeting of this Association will be held at Bethlem Hospital, London, on Thursday, May 19th, at 4.30 P.M. On that occasion Dr. Savage will read a paper on Influenza and the Neuroses. Mr. Beadles will read a paper on Gall-stones in the Insane. Members will dine together after the meeting at the Café Royal, Regent-street, at 6.30 P.M. The dissertations for the bronze medal and prize must be sent to the president not later than May 30th. The examination for the Gaskell Prize will take place in July.

Correspondence.

"Audi alteram partem."

THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editors of THE LANCET.

SIRS,—I note that the committee of the Association of Fellows has again done me the honour of asking me to stand as a candidate at the next election in July. On the occasions when I have been a candidate in past years I have had the requirements of the Fellows as the chief part of my programme, but I have always declared that the interests of the Members have largely entered into my reasons for wishing to obtain a seat on the Council. The recent behaviour of the committee of the Association of Members towards its two secretaries, and the solicitor who has so ably conducted their action (Steele *v.* Savory), has made me doubt the earnestness and wisdom of the latter Association so thoroughly that I have no longer any reason sufficient to induce me to make the sacrifice of personal comfort and professional income which a seat on the Council of the College would involve. Therefore I shall not offer myself again in July. I am, Sirs, yours faithfully,

May 4th, 1892. LAWSON TAIT.

"CURE OF STRICTURE OF THE URETHRA BY MEANS OF PHYSIOLOGICAL REST."

To the Editors of THE LANCET.

SIRS,—I regret that, owing to press of work, I should have overlooked in last week's issue Mr. Burghard's most interesting comments upon some cases of mine that were published in THE LANCET a short time ago. That organic stricture of the urethra, even when it is of long standing, can be permanently cured by external urethrotomy must be admitted, in spite of the authority of the late Mr. Berkeley Hill. Mr. Burghard's cases are, it is true, of very short duration—the longest was under two years (two of mine were eighteen and twenty-six years respectively; Bickersteth's was eighteen, and one of Syme's was thirteen); but all such evidence is of value, and this permanent cure must be attributed in very great measure, if not entirely, to prolonged physiological rest. Whether perineal drainage alone can effect the same result depends of course upon the pathological anatomy of the stricture in question; but in those instances in which the mucous membrane can be dissected off and unfolded its full width, and in which, therefore, the narrowing must be caused by the accumulation and condensation of inflammatory lymph in the submucous and peri-urethral tissues, there can be little doubt that it would be equally efficacious. I do not think much is gained by comparing a stricture of the urethra to the perforation left in the soft palate after an unsuccessful operation. I cannot see a single point in common. I do not of course advocate the adoption of perineal drainage instead of internal urethrotomy and the other well-known measures; such a course would be absurd. I merely point out that when it is advisable for other reasons, it has upon some strictures at least a most beneficial effect, causing them almost to disappear of themselves, and that this can only be attributed to the fact that it places them in a condition of complete physiological rest. I regret that Mr. Burghard's case should have relapsed so soon, but I never meant to imply that perineal drainage could be successful in every case; it could never, for example, cause the absorption of a urethral cicatrix. I am, Sirs, yours faithfully,

Wimpole-street, April 28th, 1892. C. MANSELL MOULLIN.

"OPERATION FOR SPASMODIC TORTICOLLIS."

To the Editors of THE LANCET.

SIRS,—Notwithstanding the reclamation of Mr. Noble Smith, which appeared in THE LANCET of April 30th last, I still adhere to the conviction that, as a rule, surgical operations for the relief of neurotic affections should not be performed, save in cases of strict necessity and as a last resource, and unless commended to us by "the true measure of desert, success." The object of my letter was to show that so long as the simple yet effective remedy adopted by Dr. Morton Prince had not been tried, that emergency had not arisen, and who will say that anything approaching the average success that attends ordinary surgical operations has followed the handiwork of the neurosectomists? The lengthened immunity from suffering claimed by Mr. Noble Smith for two of his patients is creditable to him, and I trust that it may long continue; but in the words of Dr. Goodhart, "if the pain return, what will he do in the end thereof?" Mr. Noble Smith's suggestion that the case related by Dr. Morton Prince was a neurosis simulating wry-neck was a mere assumption; the graphic description of the patient's suffering, her anæmia and debility, and the suspicion of the existence of caries of the cervical vertebræ, should satisfy an unprejudiced mind of the gravity of the case. It is evident that Mr. Noble Smith has not perused my papers in THE LANCET of July 12th and Dec. 6th, 1884, from which Dr. Morton Prince drew his inspiration, otherwise he would scarcely have endeavoured to belittle the importance of blistering over that limited but important region covered by the fourth and fifth dorsal vertebræ. *Apropos* of wry-neck, I may be permitted to relate the particulars of a recent case. On Wednesday, April 27th last, I was called to visit a patient. On the previous Saturday she was exposed, while lightly clad, to a cutting east wind. The result was a wry-neck in a most severe form. She suffered from continuous pain shooting down the shoulders and back, aggravated by any attempt to hold her head erect. She had not been able to lie down for the previous three nights, being compelled to sit up in bed supported by pillows. Finding that the fourth and fifth dorsal vertebræ were very painful on pressure, I applied over them the liquor epispasticus. Next day all pain had gone, neck still a little stiff; on the succeeding day full relief was experienced, and I found her attending to her ordinary house duties. It would appear, then, that if torticollis of recent date may be suppressed by a simple remedy, the necessity for a heroic operation at the end of sixteen years need not arise. I am, Sirs, yours faithfully,

ALEXANDER HARKIN, M.D.Aber., F.R.C.S.Eng.

Belfast, May 1st, 1892.

SMALL-POX TRAMPS: WHO IS RESPONSIBLE?

To the Editors of THE LANCET.

SIRS,—The case of this kind which has recently occurred in this town, as your readers know, has given rise to much squabbling which can be but of local interest; but there are features in it which must be of some general interest, if only that they should not form a precedent in public health administration to other sanitary authorities. The mayor, in his letter to you, has only quoted extracts from the infirmary chairman's letter to the medical officer of health. He has omitted to quote, "it is obvious that the man should be at once removed from the infirmary, where infectious cases are not admitted"; and "it is desirable that you should take immediate steps to deal with the case." The man appeared as a casualty in the out-patient waiting-room, brought no subscriber's recommendation, no guarantee for maintenance or removal charges, and no application was made by the sanitary authority to the "superintending body of such hospital," under Sec. 124 of the Public Health Act, for "consent" to his admission into the infirmary. In these days of enlightenment it needs no argument to show that a general infirmary with a large out-patient department is no proper place for the admission of small-pox cases or of any other infectious diseases. The so-called "fever wards" are of fifty years ago, and hardly now proper places for the adequate isolation of any infectious case which might break out in the wards of the infirmary. The word "inmate" upon the ordinary notification certificate was perhaps an unfortunate one: the man's belongings were at the common lodging-house where he had slept the previous night. The sanitary authority, however, appear to show more concern at that word than at the other—small-pox—upon the certificate. One can hardly justify the existence of sanitary authorities if it is not to use their best endeavours to protect their districts, and the inhabitants, from infection of this kind. Such certainly hitherto have generally been considered amongst the chief of their responsibilities; and the fact of a hospital for infectious diseases being available or not in no way affects these responsibilities.

Digitized by Google

The absence of an available infectious hospital only increases the difficulties of administration. To a certain extent there is reason in what the Mayor says: "that the duties of a sanitary authority, under circumstances of this kind, are most clearly defined by law"; and afterwards that he should ask you "by what authority or Act of Parliament they should have been guided." As a matter of fact, I believe that the local authority exceeded what is defined by "shall," and did what was optional and permissive—such as under Sec. 121 of the Public Health Act. They "*may* direct the destruction of bedding, clothing, &c.," which the local authority did.

This permissive word "may" which runs through the Public Health Act, and which is applied to the adoption of this Act, such as that of notification, infectious diseases prevention, &c., is the stumbling-block to healthy sanitary organisation and public health administration. It culminated here in the first instance in the local authority repudiating their responsibilities, in their endeavour to palm off their responsibilities on to one of the charitable institutions of the district. The moral to be drawn from this case is that what is now permissive in Public Health Acts and legislation should henceforth be made compulsory; and that a closer supervision should be exercised over local authorities, central in character, from the Local Government Board and through country medical officers of health, to secure adequate and uniform administration.

I am, Sirs, yours truly,
J. LLOYD-ROBERTS, M.B., D.P.H.,
Hon. Medical Officer, Denbighshire General Infirmary.

May 2nd, 1892.

*** We have expressed our views on this matter elsewhere.—ED. L.

THE VOLUNTEER MEDICAL STAFF.

To the Editors of THE LANCET.

SIRS,—I am directed by the Council of the Volunteer Medical Association to forward to you the enclosed copy of a letter sent to the Secretary of State for War, and to ask if you will publish it for the information of volunteer medical officers, and give the Council your valuable assistance in forwarding the views therein expressed.—I am, Sirs, yours faithfully,

J. EDWARD SQUIRE, M.D., Hon. Sec.,
Headquarters, London, May 4th, 1892. Surg.-Capt. V.M.S.

[COPY.]

Headquarters, 101, Great Russell-street, Bedford-square, W.C., April 21st, 1892.

SIR,—I have the honour, by direction of the Council of the Volunteer Medical Association, to inform you that their attention has been drawn to your reply of the 4th inst. in the House of Commons to a question of Col. Henry Eyre, chairman of the Departmental Committee of the War Office, which sat in 1888 to consider the medical organisation of the volunteer force, asking if it was your intention to give effect to the recommendation of that committee as follows:—"Paragraph 42. It came out in evidence that the medical officers of the volunteer force wished to be placed on precisely the same footing as other officers of the volunteers regarding the distribution of honours and rewards. We submit this to your favourable consideration."

You are reported to have stated that volunteer medical officers, if employed on active service, would be placed on the same footing as regards honours and rewards as medical officers of the regular army, but that, with the exception of rewards for active service, the only honours open to volunteer officers were those given to officers in command of regiments.

I am directed to respectfully draw your attention to the following points:—

1. That the report of the above-mentioned Departmental Committee was approved and adopted by you, and that all its recommendations have been carried out, with the exception of that contained in paragraph 42.

2. That the point of comparison drawn in the recommendation of the committee is not between the medical officers of the volunteer force and those of the Army Medical Staff, but between the medical officers of the volunteer force and the combatant officers of the same service.

To the commanding officers of the volunteer force are open such rewards as K.C.B., C.B. (both in the civil department), and A.D.C. to Her Majesty, and thus junior combatant officers have some incentive to remain with their corps in the hope of ultimately obtaining the command, and becoming eligible for such rewards; but medical officers have no such possibilities before them, and are thus obviously placed at a disadvantage.

3. If, however, a comparison be made with medical officers of the Army Medical Staff, the Council would submit that the inference to be drawn from your reply is that rewards are only open to such latter officers as a result of their being employed upon active service.

This, however, the Council would venture to remind you, is by no means the case, honours and rewards being given quite irrespective of such particular service.

The Council of the Volunteer Medical Association therefore respectfully submit the following propositions:—

1. That the medical officers of the volunteer force are at present at a disadvantage as compared with the combatant officers of the force in respect to the bestowal of honours and rewards for distinguished service.

2. That these disadvantages might be obviated by the bestowal of honours and rewards for long and efficient service similar to those given to members of the Army Medical Staff under like circumstances—e.g., Q.H.P., Q.H.S., &c.

The Council earnestly hope that you will be so good as to give the foregoing facts and suggestions your most favourable consideration.

I have the honour to be, Sir, your obedient servant,
J. EDWARD SQUIRE, M.D., Hon. Sec.,
Surgeon-Captain, Volunteer Medical Staff.

To the Right Hon. the Secretary of State for War, War Office.

CERTIFICATES OF REMOVAL TO HOSPITAL.

To the Editors of THE LANCET.

SIRS,—The enclosed is of great importance to medical practitioners, and I should like an authoritative statement from you on the subject. Under the Infectious Disease (Notification) Act the fees allowed are 2*s.* 6*d.* for private and 1*s.* for public patients. Some time since every practitioner in this town received a book of forms as the one enclosed. I wrote to the medical officer of health asking what fee was payable for such certificates, and enclose his reply. The sanitary inspector, before making arrangements for removal of a patient, calls for this second certificate. Now, Sirs, can the sanitary authority compel a medical man to fill in this certificate? Is it to be expected that medical men should fill in this certificate for no remuneration? The fees for notification have been placed as low as possible, but if this second certificate must be signed the intrinsic value of the former will amount to the enormous sum of 1*s.* 3*d.* and 6*d.* I am, Sirs, yours truly,

Plymouth, May 1st, 1892. EDWARD G. DUTTON.

Medical Officer of Health Department,
Municipal Offices, Plymouth, April 9th, 1892.

DEAR SIR,—No fee is payable for signing the certificate of removal. It is for the purpose of protecting the sanitary authority. Having a certificate of a patient's fitness for removal from a medical man removes responsibility in the event of a patient dying on the way to hospital.

Yours faithfully,
Dr. Dutton. F. M. WILLIAMS.

*** There is no power authorising the sanitary authority to require any such certificate. If they want "protecting," and their own paid officers do not protect them, they should remunerate those who do so. How far such certificates may be filled in as a matter of courtesy is another matter.—ED. L.

THE CONGRESS OF INTERNAL MEDICINE AT BERLIN.

(FROM OUR OWN CORRESPONDENT.)

AT the forenoon sitting of the Congress of Internal Medicine, on April 22nd, Professor Rosenstein of Leyden spoke on Chronic Hepatitis. In Germany, he said, the opinion still prevailed that the two morbid conditions of the liver are only different stages of the same disease, and that the stage of enlargement precedes the other. Professor Stadelmann of Dorpat declared inadequate the reasons adduced for the opinion that hypertrophy and atrophy of the liver were different diseases. Among the causes which specially favour the latter condition he mentioned the copious consumption of alcohol, chronic lead-poisoning, syphilis, tuberculosis, and malaria, but maintained that there were many cases of which it was impossible to trace the cause. Nor were the causes of jaundice, one of the most characteristic symptoms in the hypertrophic stage, sufficiently cleared up. Professor von Frey of Leipsic reported the important fact, ascertained by experiments on animals, that the jaundice which follows the closing of the biliary passages leading from the liver did not supervene if the ductus thoracicus was ligatured. Dr. Israel of Berlin reported the results of his investigations on the secondary alterations in the organs of circulation when the action of the kidneys was insufficient. Dr. Krönig of Berlin gave an account of an injecting apparatus which he had constructed. Dr Schmidt of Breslau showed microscopic preparations in which the characteristic formations of pulmonary asthma in the smaller bronchi were beautifully visible. Dr. Martius of Rostock

Digitized by Google

reported the results of a series of very careful chemical analyses, undertaken with a view to ascertaining the quantity and the manner of the appearance of the hydrochloric acid in the stomach in digestion. He stated that it is secreted in the stomach, uncombined, immediately on the entry of the food. Professor A. Fränkel of Berlin spoke on cancer of the costal pleura. Dr. Hoppe-Seyler of Kiel reported his investigations of the fermenting processes in the stomach, and of the gases developed by them under various conditions. Professor Unverricht of Dorpat discussed the manner of the occurrence of Cheyne-Stokes breathing under the influence of various poisons and morbid processes, and explained it as a symptom of cerebral collapse. The following three speakers treated of tuberculosis in connexion with the comparatively small number of cases in proportion to the enormous opportunities of infection, and arrived at the conclusion that far more people were infected than was known. In the greater number of cases the tubercle bacilli were rendered either permanently or temporarily harmless by the resistance of the tissues of the body. In the latter case they remained in the body as latent foci, which become active when the resisting power of the body diminished. Dr. Spengler of Davos reported the results of the treatment of pulmonary phthisis with tuberculin and tuberculocidin (tuberculin purified by Klebs) combined. Dr. Cornet of Berlin drew attention to mixed infections in pulmonary tuberculosis, and maintained that the dangerous feverish conditions which set in with rapid decay of the lung tissue in the course of otherwise slow pulmonary tuberculosis were not due to the tubercle bacillus alone, but to other bacteria also—streptococci, staphylococci, &c. The first speaker on the 23rd was Dr. Mannaberg. His discourse was on the subject of malaria, and he maintained that the semilunar micro-organism appearing in malignant cases were neither products of degeneration nor a definite species of disease germs, but cyst-formations produced by the fusion of two or four of the young micro-organisms in the red blood-discs, and generating new ones by sporulation. The Congress was closed by the chairman, Professor Kürschmann. Next year's Congress will meet at Wiesbaden.

Berlin, May 3rd.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The General Hospital.

THE election of a physician to fill the vacancy caused by the resignation of Dr. W. F. Wade took place on the 4th inst. The election committee consists of the committee of the hospital, *plus* fifty others chosen by ballot from the general body of subscribers. Eighty-two attended the meeting, which resulted in the election of Dr. T. S. Wilson. The numbers were: Dr. Wilson, 54; Dr. Foxwell, 16; and Dr. Short, 12.

Annual Meetings.

The present time of the year is the one usually chosen for the annual meetings of various hospitals in the city.

The annual meeting of the governors of the Skin and Lock Hospital took place on April 29th, under the presidency of Captain Grice Hutchinson. The report showed that the new cases treated during the past year (3692) had been more numerous than in any previous year. The attendances of patients numbered 24 832; the in-patient department had received 56 skin and 21 lock patients, and their average stay had been 42 days. The treasurer's statement showed a surplus of £915, increased from £626 at the end of 1890.

The annual meeting of the Ear and Throat Hospital was held on May 2nd, Lord Leigh in the chair. The forty-seventh report showed that the number of new cases was 1872—eighteen more than in 1890—the total number of cases registered for the year being 4117. The registration fees paid by the patients, upon which the hospital depends chiefly for its support, were 2249 in number, and produced the sum of £393 11*s.* 6*d.* The total number of attendances of out-patients was 13,031, and 109 cases were admitted as in-patients. The management account showed that the total receipts amounted to £816 3*s.* 4*d.*, and that there was a balance in hand of £28 4*s.* 5*d.*

At the Lying in Charity the annual meeting took place on April 27th. The chair was taken by Mr. J. D. Goodman. During the past year there had been two deaths of mothers out of 741 patients. The average number of deaths during the last ten years had been 1 in 400. The assistance of the honorary surgeon was called in twenty-one times. The number of children born alive was 725, and there were twelve deaths of children. The financial condition of the charity was recorded to be satisfactory, there being £18 in hand. The work is all extern, and done by midwives, who call upon the honorary surgeons in cases of difficulty.

The twenty-third annual meeting of the Midland Counties Idiot Asylum was held at Worcester on April 30th, the Mayor of Worcester being in the chair. The total number of patients resident during the year was 52; 3 had died, 2 were removed, and 7 new cases were admitted. The financial position was stated to be satisfactory, as there was no debt. The total income for the year amounted to £1777 15*s.* 1*d.*, and the gross expenditure, including depreciation of buildings and furniture, was £1753 12*s.* 7*d.* Special thanks were given to Lord Leigh, the president, for the constant interest he had taken in the welfare of the institution.

Deaths of Cyclists.

A young man aged nineteen suddenly expired while riding on a bicycle. Immediately before he remarked that he felt better that day than he had ever done. He had previously partaken of some "lemon and a dash." The doctor at the inquest expressed the opinion that death was due to violent exertion, particularly after taking a cold drink when the body was heated. In such a case it would have been of importance if a post-mortem examination had been made, and the cause of death accurately ascertained. So many young men exert themselves violently on the bicycle that the warning thus afforded would probably have acted as a guide to them in the pursuit of this pastime.

Birmingham, May 4th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Proposed Medical Officer for Durham County.

AT the last meeting of the Durham County Council the committee brought up a report recommending the appointment of a medical officer of health at a salary of £500 a year, with reasonable travelling expenses in addition, and that he should also hold a qualification in public health, reside in Durham, and devote his whole time to the duties of his office. The report was adopted, with the addition that the age should be limited to between twenty-five and forty-five years.

Lunacy in the County of Durham.

Dr. Smith, medical superintendent of the Durham County Asylum at Sedgefield, in his thirty-third annual report, states that up to December, 1891, 8116 patients, of whom 4346 were men and 3770 women, were admitted. Of these, 1416 men and 1116 women recovered, being at the rate of 32·5 per cent. men, and 44·3 per cent. women. Dr. Smith observes, as to these very large statistics, that the percentages of recoveries appear too small or less favourable than ought to be exhibited. The deaths give a total of 2827. A large number of patients, owing to want of accommodation, had to be transferred to and from other asylums. Dr. Smith says that the figures show broadly that a larger number of men than women die insane. This, he thinks, is almost entirely owing to the fact that a very large number of men labour under severe organic disease of the nervous system from hard living. He thinks that there is no increase in the spread of lunacy, and in support cites the following figures of the new or recent cases admitted, which were in 1860–61 1 in 3460 of population; 1870–71, 1 in 3480; 1880–81, 1 in 3309; 1890–91, 1 in 3452.

Fatality to a Westmoreland Coroner.

Mr. Thomas Wilson, Mayor of Appleby and coroner for the east and west wards of Westmoreland, was on Friday last killed by being thrown from his horse at Sedburgh, where he was on a visit.

Sunderland.

During the past week the sum of £500 has been given to the Sunderland Infirmary and £100 to the Monkwearmouth and Southwick Hospital under the will of the late Mr. R. T. Wilkinson of Sunderland. During the last few weeks

Digitized by Google

the export trade of Sunderland has been rapidly declining, owing to the strike, in the matter of coal from thousands to hundreds of tons; but for the week ending last Thursday matters reached their worst, when not a single ton of coal was exported, an occurrence which is probably unparalleled in the history of the port. The annual report of the Northumberland and Durham Miners' Permanent Relief Fund has been issued, in which it is stated that there have been 167 deaths from accidents, which is nearly 1·5 per 1000 members, being a small increase on that of last year. Eleven of those on the Permanent Relief Fund amongst the deaths had been receiving relief for some years. It states that the present benefits cannot be kept up unless the payments are increased, and that no amount of care of the fund can make a sovereign worth more than twenty shillings. It is, moreover, unsatisfactory to learn from the same report that the present strike in the county of Durham is costing the fund about £2400 per fortnight.

Eston, Middlesbrough.

Reference was made at the last meeting of the Eston local board to the high mortality lately prevalent in the district, which the medical officer, Dr. Malcomson, attributed to the outbreak of measles in the district, to counteract which measures were being taken to close the schools in the affected district. Dr. Barry, it was reported, had approved of the proposed sanatorium, subject to a few alterations which had been suggested by him.

Dr. H. E. Armstrong on Infectious Diseases.

Dr. H. E. Armstrong gave a lecture on Saturday last (in continuation of the course) on "Infectious Diseases." There was a crowded audience. Mr. Alderman Winter, the chairman of the City Health Committee, presided. Dr. Armstrong dwelt very fully on the media by which infectious diseases might be conveyed. Of all foods he thought milk was the most subtle and most at fault in spreading infectious diseases. He also spoke of other modes of infection—viz., air, water, clothing, and direct contact.

Charitable and other Bequests.

Mrs. Mary Robinson, widow, late of Cockermouth, amongst other charitable bequests, left £100 each to the Carlisle Infirmary and the Carlisle Dispensary. — Miss Emily Sarah Wilson, late of Dalham Tower, whose will has been proved at Carlisle, left, amongst other charitable bequests, £100 to the Royal Asylum of St. Ann's Society, Redhill, Surrey.—The late Dr. Carlyle of Carlisle, whose will has been proved at Carlisle, the gross personalty being under £9000, left his collection of specimens of fungi to the Royal Herbarium Museum at Kew, and some works on fungi to the Carlisle Corporation Museum which is to be shortly formed.—It is freely rumoured in this city that the late Dr. Heath left a large sum of money for a specific purpose in connexion with the Newcastle College of Medicine of the University of Durham.

Newcastle-on-Tyne, May 4th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

The Sanitary Condition of Peterhead.

AT a meeting of the Peterhead section of the Buchan Field Club recently Dr. Middleton delivered a lecture on Bacteria and Epidemics, in the course of which he referred to the apathy towards sanitation evinced in Peterhead. He thought Peterhead had a share of epidemics rather above the average, for which there were several reasons. Some of the houses were a disgrace to civilisation. There were dens of squalor, dirt, and misery, all retarding the health of the community. Again, in the summer fishing season they had a large increase in the population, some of them not very sanitary either in their persons or habits, and living under most insanitary conditions, overcrowded in dirty, unventilated garrets. Again, when they did have an outbreak of disease in Peterhead, so far as the authorities were concerned, it got leave to revel unrestrictedly. In fact, they lived and moved in Peterhead as if there had been no such thing as a science of public health, as if enactments for the preservation of health had never taken place, as if these things were altogether apart from them and their every-day concerns. They as a community were not so far in the rear of their neighbours in any intellectual pursuit. Why, then, should they so linger in a matter of such vital importance? Why should precious lives be imperilled? Or why should bodily and mental suffering be incurred that might have been prevented?

Insanitary Condition of Boddam.

Dr. Watt, medical officer of health for Aberdeenshire, in a verbal report to the Public Health Committee of the County Council on the sanitary condition of Boddam, strongly condemns the present state of affairs in the village. Hardly a year passed without an outbreak of scarlet fever, and there had been a number of outbreaks of typhoid fever within recent years. There were three causes for this: First, the fact that since 1873, when the drains were laid, not one of them had been flushed, and the manholes were cleaned only once in two years. In the next place, there was a very extraordinary deficiency in trapping; and, in the third place, there were five huge pits of offal which were situated most suitably for distributing their effluvia to the houses. The fishermen would be only too pleased to have the state of matters improved, even at a pecuniary loss. Stonehaven was an example of improved sanitation worth copying. Dr. Watt is hopeful of the result of the meeting of the committee of fishermen and of the County Council.

Aberdeen Royal Infirmary: Resignation of Dr. Ogston.

At a meeting of the directors of this infirmary on April 27th the formal announcement of Dr. Ogston's resignation of his post of surgeon was read; also communications embracing resolutions passed by the medical faculty of the University, by the meeting of medical men held in Dr. Ogilvie Will's house, and by mass meetings of medical students, all expressing their anxiety for Professor Ogston's withdrawal of his resignation. The board then received the deputation from the meeting of medical men—namely, Dr. Ogilvie Will, Dr. Henry Jackson, Mr. Alex. Profeit, and Dr. Alex. MacGregor. Dr. Will read the resolutions passed at the meeting of medical men (which were printed in THE LANCET a fortnight ago), and thought these were not at all overstated. He thought Dr. Ogston's position in the infirmary as a practical surgeon, as a scientific man, and as a clinical teacher could not be overestimated. Dr. Ogston was not a man of mere local celebrity, but a man of world-wide fame, and his attachment to the infirmary gave it a different status from what it would otherwise occupy. Dr. Jackson said that the directors should make every effort to get Dr. Ogston to reconsider his resignation. The loss of a surgeon who has made such a reputation for himself, and who was held in the highest esteem by his brethren throughout the country, would, said Dr. Jackson, seriously affect the popularity of the institution, and that would result in financial loss. If the popularity of the infirmary was to be maintained, they must have the very best men on the staff, and the directors ought to do all they possibly could to make it possible for Dr. Ogston to withdraw his resignation and resume his duties as senior surgeon. Mr. Profeit also strongly urged the directors to do their utmost to retain Dr. Ogston's services. Dr. MacGregor remarked that while it might be a matter of opinion whether ehe public would have the same confidence in the institution without Dr. Ogston, it was not a matter of opinion with the profession. It was a matter of fact that they could not have the same confidence in the hospital if Dr. Ogston resigned. The chairman of directors then said they heartily concurred in all the deputation had said, and the board unanimously adopted the following resolution:—"The directors of Aberdeen Royal Infirmary, fully recognising the eminent skill and high reputation of Professor Alexander Ogston, and the great value of his services to the hospital, have received with deep regret his resignation as senior surgeon. The directors sympathise most heartily in the efforts being made to induce Dr. Ogston to reconsider his decision to retire from infirmary duty, and they will be much gratified to find that these efforts prove successful."

Resident Assistants.

The following gentlemen have been appointed to fill the posts of resident assistants in the Royal Infirmary for the year beginning May 1st:—James Rush, M.A., M.B., C.M.; W. R. Pirie, M.A., M.B, C.M.; Duncan D. Macintosh, M.B., C.M.; and W. M Anderson, M.B., C.M.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Royal College of Surgeons.

AT a meeting of the Fellows, presided over by Mr. Croly, on Monday, May 2nd, Mr. F. Alcock Nixon was elected a member of council. He was opposed by Dr. Parefoy, the votes given being 90 and 38 respectively. The election for examiners usually takes place the first Monday in May, but may be deferred at the wish of the council, and this year it will be held on Friday, the 20th inst. There will be ten examiners appointed to examine for letters testimonial and Fellowship; three for the diploma in midwifery; four for the diploma in Public Health; six for the diploma in dentistry, and two to examine in general education. A meeting of the Fellows will be held on Saturday, June 4th, to receive the annual report of the council; and on the 6th prox. a meeting will take place, pursuant to the provisions of the charters, to elect a president, vice-president, council, and secretary for the ensuing year. Mr. Croly's term of office having expired, he retires, and will be succeeded in the presidency by Mr. Edward Hamilton, professor of surgery in the College schools, surgeon to his Excellency the Lord Lieutenant, and surgeon to Steevens' Hospital. Mr. Thornley Stoker, surgeon to the Richmond Hospital, it is confidently expected, will be elected vice-president without opposition, in the room of Mr. Carte, J.P.

Poisoning by Nitric Acid.

A fatal case of poisoning by nitric acid occurred last week in Dublin. A grocer named McNally swallowed a quantity of the acid—probably the strong acid—while partially intoxicated, on the morning of the 28th ult., and within a few minutes was removed to the Meath Hospital, where he died about ten hours afterwards. The post-mortem examination showed that the stomach was corroded and destroyed. The coroner's jury brought in a verdict that the deceased died from shock, consequent on drinking strong nitric acid, while under the influence of alcohol.

Coombe Lying-in Hospital.

The governors last week, on the nomination of the master, appointed Dr. George Cole-Baker assistant master to the hospital. He is a bachelor in medicine, surgery, and obstetrics of the University of Dublin.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Results of the Application of Lannelongue's Sclerogenic Treatment in Tuberculous Affections.

AT the French Surgical Congress M. Coudray furnished a highly interesting report on the results of the application of the new method of treating surgical tuberculous diseases devised by Professor Lannelongue. His report is founded upon sixty cases, including thirty-one of affections of the larger joints, nine of the lymphatic glands, six of the foot and fingers, and four of the spine. The results are stated to be excellent, recovery from the local lesion being the rule, and the propagation of the bacillus to distant parts being prevented through the formation of the sclerogenic barrier due to the chloride of zinc. What is the fate of the bacilli in their conflict with the new elements generated around the territory occupied by them? M. Coudray opines that they perish, or that, at any rate, their activity is paralysed. This opinion is based upon three microscopical examinations he has conducted on extirpated masses, and on the negative results of inoculations. M. Lannelongue explains the apparition of certain abscesses some time after the injection of the chloride of zinc solution by supposing that the bacillus colony is encapsuled temporarily. It is also possible that certain lesions may accidentally escape the action of the remedy. In a previous letter I wrote of the treatment of congenital dislocation of the hip-joint by Lannelongue's method. M. Coudray tells us that a little girl of three years, thus treated five months ago, has now began to walk, her lameness having diminished considerably. The femoral head now reaches during adductory and internal rotatory movements only to a point one centimetre above the line of Nélaton-Roser, instead of three centimetres, the point reached before treatment. M. Coudray has also essayed the method in the combating of such hopeless diseases as malignant tumours. Applied in three instances (two generalised malignant lymphadenomata and one cancer of the breast) the size of the growths seemed to be materially diminished and their development arrested. The difficulty is to circumscribe the infected lymphatic glands. MM. Ivesco of Paris, and Dubois of Cambrai cited cases of surgical tuberculosis cured by them by means of the sclerogenic method, the practice of which will, doubtless, in time diffuse itself all over the civilised world.

A New Medical Senator.

M. Labbé, the well-known Paris surgeon, has just been elected Republican senator of the Department of Orne. At the annual banquet of the *internes* of the Paris hospitals, held on the 23rd ult., under the presidency of the veteran dermatologist, Professor Hardy, that staunch defender of nursing (religious) sisters, Dr. Desprès, one of the deputies for the metropolis, deplored the fact that the vast majority of the substantially numerous medical phalanx forming part of the Lower House took no interest whatever in medicine and the welfare of its votaries. M. Labbé, will not assuredly, as a member of the Upper House, deserves to be classed in this category. With his distinguished fellow-Senator, Professor Cornil, he will, I make bold to assert, watch closely the interests of the body of which they are both such distinguished ornaments. It is a curious circumstance that M. Labbé succeeds a *confrère*, the late Dr. Libert, in the senatorial representation of the Orne constituency.

Paris, May 4th.

Obituary.

THOMAS BRAMAH DIPLOCK, M.D., M.R.C.S.

THE late Thomas Bramah Diplock was born at Hastings on May 14th, 1830. His father and mother died when he was a few months old, and his uncle, the late John Joseph Bramah, engineer, adopted him and brought him up. When he first started in life he took up engineering, at the wish of his uncle; but, always having had a great desire to belong to the medical profession, he gave up engineering, and was apprenticed as a medical pupil to the late Dr. Bennett of Shaftesbury. Afterwards he studied at St. George's Hospital, St. Mary's Hospital, and Mr. Lane's School of Anatomy. He obtained his M.R.C.S.Eng. in 1853, and M.D. St. Andrew's in 1856. He was then appointed house surgeon to the Lock Hospital, Harrow-road, and afterwards started the practice of medicine at Brompton, in partnership with the late Robert Sannemann, F.R.C.S., and continued in practice until just before he was elected coroner for Middlesex in 1868. In his election for the coronership he was opposed by the late Dr. Hardwick, but, after a close fight, was returned at the head of the poll. For nearly twenty-five years he carried out his duties as coroner without fear or favour, and gained the love and respect of all he came in contact with. When he was first attacked with cancer of the tongue he kept the knowledge that he was so afflicted to himself for nearly two years, until the disease had made such headway that he was obliged to tell his wife and family. He bore his sufferings with great fortitude and without a murmur, and passed peaceably away on April 29th, 1892, from hæmorrhage at the base of the tongue, leaving a widow, four sons, two daughters, and a large circle of friends to mourn their loss. Never was there a more devoted husband, a kinder father, or a more sincere friend. He was attended in his last illness by several medical friends, and his son, Mr. Leonard B. Diplock.

PROFESSOR WILHELM BRAUNE (LEIPSIC).

WE regret to announce the death of Dr. Wilhelm Braune, Professor of Anatomy in the University of Leipsic, who was perhaps the greatest authority on topographical anatomy of the present age, and whose "Atlas of Human Topo-

Digitized by Google

graphy," also published in a reduced form in 1874, and ably translated into English by the late Mr. Edward Bellamy—dealing as it does with frozen sections—is one of the most important works which have been published in that particular branch of the subject. His illness was of short duration. On Friday week he was in his laboratory, where he caught a chill, which prevented his attendance on the Saturday. Pneumonia gradually supervened, and he died on Friday, April 29th, in the sixty-first year of his age. Professor Braune was a man of fine presence and winning manners, and to the students of anatomy who studied at Leipsic his kindness was extreme and his courtesy was unfailing. He paid every consideration to the work of foreign students in his laboratory, and many of our own countrymen owe much to his wise advice and direction. At the time when his illness came upon him he was engaged in superintending the researches of Dr. Hughes, lecturer of anatomy in the Edinburgh Extra-mural School of Medicine, on the movements of the spinal column, a work in which he was specially interested. Even on his deathbed on Tuesday last he threw out several suggestions as to how the work should be completed. He was a scion of an ancient line of medical men; his father and his grandfather before him had devoted themselves to the healing art. He had also strong literary tastes, and was joint editor, with Professor His, of the *Archive of Anatomy*, published in Leipsic. He made many friends in England during his visit in 1881, when he attended the International Medical Congress.

GEORGE HOGARTH MAKINS, M.R.C.S., L.S.A.

MR. MAKINS died on April 12th. He was born in 1815, and his father, an official in the Treasury, died when his son was ten years of age. Mr. Makins' early tastes inclined to the study of chemistry, but the difficulties in the way of taking up this branch of science in those days were so great that his mother thought the nearest approach would be to apprentice him to a country medical man. He was therefore apprenticed to Mr. Norton of Uxbridge, afterwards entered as a student at King's College, London, and St. George's Hospital, and took his L.S.A. in 1839, becoming M.R.C.S. in 1840. Mr. Makins then being free to follow his own tastes, took up the study of chemistry, and held successively the chair of Chemistry at the Aldersgate School of Medicine and the Middlesex Hospital. At this time he became specially interested in the metallurgy of the precious metals, and this eventually led to his starting an assayer's laboratory. As an assayer he enjoyed an unrivalled reputation, acting as referee on many occasions between the Bank of England and the Mint, and while employed in this way he thoroughly remodelled the whole process. During a period of twenty years he gave an annual course of twelve lectures on metallurgy at the Dental Hospital of London. When the Society of Apothecaries altered the relation of the Society to the Old United Stock-holders, Mr. Makins took an active part in the proceedings, and was shortly afterwards elected a member of the Court of Assistants, serving the office of master in 1889. His excellent business capacity and good judgment were of great service to the Society in a somewhat critical period of its history. Although not practising medicine, Mr. Makins took a hearty interest throughout his life in the education of medical students in chemistry, and he was known and beloved for his personal characteristics by a wide circle in the profession.

CHELSEA HOSPITAL FOR WOMEN.—Earl Cadogan, K.G., presided over the 21st annual meeting of this charity. The report showed that the annual subscriptions for the year were £1956 9*s.* 6*d.*, and the donations £782, while £600 had been received in bequests. It was stated that the festival dinner held in May brought in over £1000. The nursing staff had benefited, too, by a series of lectures given by the medical staff.—The convalescent home at St. Leonards, which was opened on June 3rd last, was said to be doing excellent service, and already, out of the nine wards, seven had been named by donors of £105 and upwards.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen, having conformed to the by-laws and regulations and passed the required examinations, were at the meeting of the College on April 28th admitted Licentiates:—

*Abbott, Fred. W., Charing-cross.
Agar, Morley Frederick, London.
Anderson, J. Buckle, St. Barthol.
Ansorge, Wm. John, St. Barthol.
Arathoon, Hilary C., St. Barthol.
Argyle, Stanley S., Melbourne.
Atkinson, Jackson A., St. Mary's.
Bakewell, R. Turle, Univ. Coll.
Barberi, José Ignacio, Liverpool.
*Berridge, William Robt. Morpott, St. Thomas's.
Bird, W. E. Frankish, London.
Birdwood, G. T., Camb. & Guy's.
Bligh, William, Guy's.
Bowring, Walter A., St. Thomas's.
Boyd, Alex. Brooke, St. Barthol.
Bromhall, Ernest, Birmingham.
Brown, Stanley M., Manchester.
Browning, George Dansey, Rennes and Westminster.
Bubb, William, St. Bartholomew's.
*Cade, H. Lowless, St. Thomas's.
Campbell, Arthur Minton, Oxford and St. Thomas's.
Carre Smith, H. L., Charing-cross.
Colclough, William Frank, Guy's.
Croft, J. T. Herbert, St. Barthol.
Crossing, Augustus V., St. Mary's.
Cummings, H. Joseph, Toronto.
Daniel, R. Napier, St. Thomas's.
Davies, Gwilym C., St. Barthol.
Dow, W. Alexander, St. Barthol.
Easton, F. Edward, St. Mary's.
Elliott, Charles Caldwell, Guy's.
Emery, Arthur, Birmingham.
Evans, John Richard, Guy's.
Foster, Michael B., Charing cross.
Frazer, Ernest Edward, Guy's.
Fuller, Chas. Arthur, St. Mary's.
Fullerton, A. Young, Univ. Coll.
Garman, John B., Birmingham.
German, Arthur Wm., Liverpool.
Gideon, G. Vernon M., St. Mary's.
Gilpin, Bernard B., King's Coll.
Gowring, B. W. N., St. Barthol.
Grant, Charles Wm., St. Barthol.
Greaves, Edward Harrison, Guy's.
Gross, Phineas, Leeds.
Hake, James, London.
Hanham, Leonard L., St. Barthol.
Harcourt, C. Harold, Birmingham.
Harper, Walter J., St. Thomas's.
Harris, Jas. Edward, St. Thomas's.
Harvey, Arthur George, Cambridge and Charing-cross.
Harvey, John, Liverpool.
Harvey, John Owen, St. Barthol.
Hatch, Herbert L., St. Mary's.
Heaton, A. Frederick, St. George's.
Hey, H. D., Durham & St. Mary's.
Hill, Ernest, Middlesex.
Hocken, James P., Charing-cross.
Hughes, E. Lucas, Univ. College.
Isaacs, E. Percival, St. Thomas's.
Jackson, R. Houlton, St. Barthol.
Jager, Harold J., King's College.
James, Ernest W., King's College.
*Jones, H. Hepburn Averay, Lond.
Jones, H. J. Rutherford, London.
Kendall Bernard Charles, Bristol.
Kendrick, George, Birmingham.
King, John Charles, Westminster
Landon, Ernest E. Balman, Guy's
Lattey, Arthur Jas., St. George's
Loveday, Wm. Dunmore, Guy's
MacGrath, E. John, S. George's.
Mackenzie, Kenneth M., London.
Makalua, M. Manuia, King's Coll.
March, Edward Gerald, Guy's.
Master, G., Camb. & St. Barthol.
May, Percival Marshall, Guy's.
Mellor, George Mullins, Leeds.
Mercer, W. Bracewell, Cambridge and St. Bartholomew's.
Morgan, Wm. Holmes, Middlesex.
Morice, C. G. Frederick, Guy's.
Morris, F. Temple, Univ. College.
Moseley, C. Kingdon, St. Barthol.
Motteram, H. P., Birmingham.
Noble, Frank Stanley, Univ. Coll.
Nunes, Herbert Fitz-Stephen, St. Mary's.
Oliver, Thomas, King's College.
Orr, Walter Hood, St. Barthol.
Paling, A., Glasg. and Middlesex.
Palmer, Wm. M., Charing-cross.
Paton, R. McIver, Charing-cross.
Peake, George Arthur, Bristol.
Pickthorn, E. Butler, St. George's.
Pollock, John R. Russell, Guy's.
Pond, Francis A., St. Barthol.
Prada, Enrique, King's College.
Rayner, David Charles, Bristol.
Rayson, Herbert Knights, Guy's.
Read, Arthur Wm., St. George's.
Rivers, John H., St. Barthol.
Ryde, Cyril Alexander, London.
St. John, Alex. Story, Bristol.
Saffery, Frank Golder, Guy's.
*Scott, Thomas Graham, Guy's.
Senior, E. Westall, St. Thomas's.
Shearer, D. Francis, St. Thomas's.
Sheen, Alfred William, Guy's.
Sichel, G. T. Sylvester, Guy's.
Sims, David, St. Thomas's.
Smith, Abraham Arthur, Leeds.
Smith, Walter W., St. Barthol.
Stead, Dryden, Birmingham.
Stearn, Frederick Charles, Guy's.
Sworn, Ernest Andrew, Univ. Coll.
Thompson, Patrick O., St. Barthol.
Thyne, Jas. Andrew, Edinburgh.
Tibbetts, T. Major, Birmingham.
Tildesley, J. P., Birmingham.
Tootal, John H., St. Barthol.
Twynam, A. E. E., Univ. College.
Waithard, Robert Rudolf Max, Berlin, Wurzburg, and Berne.
Warneford, S. W. C., Birmingham.
Waters, G. W. B., Univ. College.
Watts, J. Alex. W., Manchester.
Wason, R. Llewhellin, Guy's.
Weir, A. Nesham, St. Barthol.
West, Henry William, London.
*Wetherall, P. Sim B., Univ. Coll.
Wheeler, C. Edwin, St. Barthol.
Wilks, S. Longmore Butterworth, Leeds.
Williamson, John, St. Barthol.
Wilson, A. Marius, St. Thomas's and Durham.
Wright, W. Charles, Manchester.

* Candidates who have not presented themselves under the regulations of the Examining Board.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE. At the Convocation held on April 30th the following candidates received the degrees indicated:—

Doctor in Medicine for Practitioners of Fifteen Years' Standing.—James Charlesworth, M.R.C.S., L.R.C.P. Lond., L.S.A.; Cautley Dawson, M.R.C.S., L.R.C.P. Lond.; William Donovan, L.R.C.P., L.R.C.S. Edin.; Stanley Augustine Gill, B.A. Dub., M.R.C.P. Lond.; Thomas Horne, L.R.C.P., L.R.C.S. Edin.; Frederick Daniell Miller, M.R.C.S., L.R.C.P. Lond., L.S.A.; Rees G. Price, L.R.C.P. Edin., L.F.P.S. Glasg.; William Henry Putsey, M.R.C.S., L.S.A.

Doctor in Medicine.—Andrew Paige Arnold, M.B., B.S. Durh., Wm. John Burleigh Robinson, M.B. Durh.; Charles Alfred Dalgliesh, M.B., B.S. Durh.; Charles John Evers, M.B. Durh., M.R.C.S., L.S.A.; Harry Fowler, M.B. Durh.; James Hindhaugh, M.B., B.S., L.S.Sc. Durh.; Ernest Beddoe Hulbert, M.B. Durh., M.R.C.S., L.R.C.P. Lond.; John F. Johns, M.B. Durh., M.R.C.S., L.R.C.P., D.P.H. Lond.; W. Lansdale, M.B. Durh., M.R.C.S., L.R.C.P. Lond., L.S.A.; Albert E. Martin, M.B. Durh., M.R.C.S., L.R.C.P. Lond.; John Worden Sandoe, M.B., B.S. Durh., M.R.C.S., L.R.C.P. Lond., L.S.A.

Master in Surgery.—Raymond Henry Shaw, M.B., B.S. Durh., College of Medicine, Newcastle-on-Tyne.

Digitized by Google

Bachelor in Medicine.—F. Burchett Rutter (Second Class Honours), London Hospital; James Alexander Wood Watts (Second Class Honours), M.R.C.S., L.R.C.P. Lond., Owens College; Duncan Jas. Caddy, Henry Augustus Collinson, Taylor Dixon, Frank Hawthorn, William Martin, B.A., Arthur Alexander Joseph McNabb, Edgar Mitchell, James Peacock, Colvin Burslem Smith, and R. Sterling, B.A., all of the College of Medicine, Newcastle-on-Tyne; Allan Gordon Russell Cameron, St. Mary's Hospital; Henry Arthur H. Claridge, Queen's College, Birmingham; Percy Coleman, M.R.C.S., L.R.C.P. Lond., St. Thomas's Hospital; Sodeinde Akisiku Leigh-Sodipo, University College, London; Hubert Llewellyn Rutter, M.R.C.S., L.R.C.P. Lond., London Hospital; Louis George Charles Vintras, M.R.C.S., L.R.C.P. Lond., B.Sc. Paris, St. Mary's Hospital.

Bachelor in Surgery.—Allan Gordon Russell Cameron, St. Mary's Hospital; Henry Arthur H. Claridge, Queen's College, Birmingham; Percy Coleman, M.R.C.S., L.R.C.P. Lond., St. Thomas's Hospital; Henry Augustus Collinson, Taylor Dixon, Frank Hawthorn, Wm. Martin, B.A., Arthur Alexander Joseph McNabb, Edgar Mitchell, James Peacock, and Robert Sterling, B.A., all of the College of Medicine, Newcastle-on-Tyne; James Alexander Wood Watts, M.R.C.S., L.R.C.P. Lond., Owens College; Francis Burchett Rutter, London Hospital; Hubert Llewellyn Rutter, M.R.C.S., L.R.C.P., London Hospital.

The Licence in Sanitary Science was received by

Cornelius Scamp Hall, M.R.C.S., L.S.A.

ROYAL UNIVERSITY OF IRELAND.—The following candidates have passed the Second Examination in Medicine of the University:—

Upper Pass Division.—Richard Allan, *Emily Eberle, Thos. D. Luke, *Edward P. McLoughlin, Jeremiah O'Callaghan, *Tim. J. O'Meara. (Those marked with an asterisk may present themselves for the further examination in Honours.)

Pass.—Robert H. Allan, William T. Allan, Joseph D. Boyd, James Cunningham, William J. Forbes, David Henry, Mortimer Hynes, Joseph Lowry, Denis McCarthy, Joseph McGrath, Robert A. McLaughlin, James Munce, Daniel J. O'Connor, David O'Donnell, Jeremiah Reidy, John D. Rice, William D. T. Thompson, Joseph H. Whittaker.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND: CONJOINT SCHEME.—The following candidates have passed the Third Professional Examination:—

H. C. Beasley, M. S. Bell, O. W. Elsner, H. C. Falkiner, G. A. Fleming, J. V. Griffin, A. A. Hargrave, R. H. H. Hayden, T. W. P. Hayes, C. A. Hayman, A. X. Lavertine, P. J. Liston, G. F. J. Luther, W. L. Martin, J. H. Maunsell, A. E. McCann, W. F. A. McCann, H. J. McCormack, C. J. Nally, W. O'Donnell, P. Peacocke, F. W. Perry, J. C. Perry, W. G. Posnett, T. Redahan, J. Robinson, N. J. Townsend, A. H. White, W. A. E. Wells, Thos. Wilson, T. F. Wyse.

METROPOLITAN OPEN SPACES.—The London County Council has acquired possession, at a cost altogether of £51,310, of the Homestall Farm, Peckham Rye, comprising nearly forty-nine acres—an addition to the Rye which raises the acreage to 100 acres.

LITERARY INTELLIGENCE.—Messrs. Crosby Lockwood and Son will issue next month the second edition, carefully revised and considerably rewritten, of "Our Temperaments, their Study and Teaching—a Popular Outline," by Alexander Stewart, F.R.C.S. Edin. To the portraits of the first edition those of Pope and Sterne, with quotations showing the association of mental with physical characteristics, have been added, and chromo-lithographs from drawings by Lockhart Bogle of temperaments very often seen appear for the first time. Indices have also been added.—We have received a copy of the first number of *Sala's Journal*, a new "weekly magazine for all." The name and photograph on the title-page afford a sure guarantee that the new journal will appeal to a very large constituency. Mr. Sala is evidently bent on combining instruction with amusement. He cannot do better; for people require to be educated in physiological truths even more than in philosophy. By teaching them how to be *gourmets* and not *gourmands*, in literary pursuits as well as in gastronomics, much nervous energy will be conserved and tranquility of mind induced. Mr. Sala's *Journal* has commenced well, and quotations from THE LANCET have found a place in its columns. He will perhaps pardon us for a suggestion relative to the outside of his journal. In colour it is too suggestive of the "pale primroses that die unmarried." It is certainly distinctive, but without appealing to the æsthetic sense. We have a vivid recollection that some sixty years ago a medical contemporary, playfully called by the editor of THE LANCET the "Yellow Goth," suffered much at the hands of certain evil disposed persons on account of the colour of its covers, and was finally forsaken by the profession. We feel sure that in the hands of so able and well-known a journalist better things will come of *Sala's Journal*.

FOOTBALL CASUALTY.—Last week, during a game, at Letterkenny, Donegal, a young man fractured his leg.

A CENTENARIAN.—Mrs. Eliza Allison has just died at Chapel House, Richmond, at the age of 101. She was born on the 20th of August, 1790, and enjoyed good health until a short time before her death.

GLASGOW SOUTHERN MEDICAL SOCIETY.—At an ordinary meeting of this Society held on April 28th, (Dr. Alexander Miller president), Dr. Peter Fergusson, was unanimously voted the diploma of the Society on the occasion of his leaving Glasgow to commence practice in the Western States of America. This is only the third time that this honour has been conferred on a member of this Society since its foundation nearly sixty years ago.

PROSECUTION UNDER THE PHARMACY ACT.—At Leicester a case of considerable importance to chemists was heard in the County Court, when the Pharmaceutical Society conducted a prosecution under the Pharmacy Act, 1868. It appears that the defendant, an unqualified man, sold a preparation of opium to an officer of the Society, which, however, was dispensed by a qualified man employed by him. His Honour decided that the defendant had incurred the penalty under the Act, and gave judgment for £5 and costs.

PRESENTATION.—Professor J. M'Fadyean, of the Royal (Dick) Veterinary College, Edinburgh, was on Monday presented, on the occasion of his leaving (having been appointed to the post of Dean of the Royal Veterinary College, London), by the teaching staff, past and present pupils of the college, and other personal friends, with an illuminated address, a silver tea and coffee service, and a gold watch. Professor McFadyean, prior to his becoming M.R.C.V.S., took the degrees of M.B., C.M., B.Sc., in the University of Edinburgh.

ASYLUM FOR IDIOTS, EARLSWOOD, REDHILL.—The annual report shows that during the past year steady progress in the work of the institution has been made in all the departments. Cases from all classes in society were applying for admission. Scientific modes of training, both physical and mental, were marked with complete success, and 2810 patients had been under the care of the institution, during the forty-five years of its existence. The anniversary festival took place at the Savoy Hotel on Tuesday, Mr. Alderman Faudell Phillips presiding. In proposing the toast, the "Earlswood Asylum, the Board of Management and the Staff," the chairman earnestly advocated the claims of the asylum for generous public financial support. The subscriptions announced amounted to upwards of £2000.

MEDICAL PROTECTION SOCIETY.—The first annual general meeting of the London and Counties Medical Protection Society, Limited, was held on Monday, April 25th. The objects of the Society are to protect, support, and safeguard the character and interests of legally qualified medical and dental practitioners. The general meeting unanimously expressed its belief in the desirability of establishing such a society. The Society dates the commencement of its operations from May 1st, 1892, and the annual subscription of 10*s.* becomes due in advance on May 1st in each year. The following is a list of the officers and Council of the Society, but the list of vice-presidents is not yet complete. President: Jonathan Hutchinson, LL.D., F.R.C.S., F.R.S. Vice Presidents: F. H. Alderson, M.D.; D. Balding, F.R.C.S., J.P., Royston; Geo. Anderson Critchett, M.D., F.R.C.S. Edin.; H. Radcliffe Crocker, M.D., F.R.C.P.; T. Colcott Fox, M.B., F.R.C.P.; H. S. Goude, M.D., F.R.C.S. Edin.; C. J. Hare, M.D., F.R.C.P.; Chas. Scott Kilner, M.B., Bury St. Edmunds; John Williams, M.D., F.R.C.P., and others. Council: E. C. Beasley, F.R.C.S., Hampstead; Andrew Clark, F.R.C.S.; W. Bruce Clarke, M.B., F.R.C.S.; C. M. Fegen, L.R.C.P. Edin., Brandon, Suffolk; George Henty, M.D.; Jonathan Hutchinson, jun., F.R.C.S.; E. Hooper May, M.D., F.R.C.S.; J. Knowsley Thornton, M.B., C.M.; and C. S. Tomes, M.A., F.R.S. Treasurer: Geo. A. Heron, M.D., F.R.C.P., 57, Harley-street, W. Hon. Secretaries: George B. Mead, Mentmore, Newmarket, and Hugh Woods, M.D., 11, Archway-road, Highgate, N.

THE COTTAGE HOSPITAL, WARMINSTER.—A new wing to this hospital was formally opened last week.

RESIGNATION OF A MEDICAL OFFICER.—Mr. F. M. Corner has resigned his position of medical officer of health to the Poplar District Board of Works, on the ground that recent legislation, notably the Public Health Act, has so increased his duties that he cannot conscientiously fulfil them.

WELLINGTON COLLEGE.—It is said that the sanitary works at the College, under the supervision of Mr. Rogers Field, C.E., are now, in all substantial points, nearly completed, including extensive surface and subsoil drainage of the estate. Notice has been given, with Mr. Field's sanction, that the school will reassemble at Wellington College on Tuesday, May 10th.

METROPOLITAN ASYLUMS BOARD.

MEDICAL NOTES IN PARLIAMENT.

Prison Surgeons.

IN the House of Commons, on April 29th, Dr. Clark asked the Secretary to the Treasury whether it was the case that the surgeons of Northampton Prison, with a daily population of 104 and commitments of 1140, and Shrewsbury Prison, with a daily population of 95 and commitments of 1290, each received a salary of £110 per annum, while the surgeons of Dundee Prison, with a daily population of 109 and commitments of 3760, and of Ayr Prison, with a daily population of 70 and commitments of 1750, received respectively £80 and £70 per annum; why the salary of the Ayr Prison surgeon had been reduced; and under what rules were these salaries determined. Sir J. Gorst: I have no information to enable me to check the accuracy, or otherwise, of the numbers quoted. The salary at Ayr was recently revised, on the death of the former surgeon, so as to correspond more closely to the present scale at other prisons in Scotland. The salaries of prison surgeons in Scotland who do not give their whole time to the public are fixed, so far as possible, with reference to the number of commitments and daily average number of prisoners at the time when the surgeons are appointed, a maximum of £90 being fixed in accordance with the recommendation of a committee which sat in 1879.

Small-pox in the West Riding.

Dr. Tanner asked the President of the Local Government Board whether his attention had been called to the fact that an epidemic of small-pox now prevailed in Dewsbury, Batley, and the neighbourhood known as the heavy woollen district, and had led to heavy local expenditure in providing for the necessities of the case; whether complete isolation of persons capable of spreading infection was attended to, and whether the origin of the epidemic could be traced to inefficient vaccination.—Mr. Ritchie: I am aware that there has been an outbreak of small-pox in the district referred to in the question. The Town Councils of Dewsbury and Batley have provided some hospital accommodation, but I cannot state that the arrangements in the district are such as adequately to provide for the complete isolation of all persons capable of spreading infection, although the necessity for providing such means of isolation has on several occasions been urged on the sanitary authorities by the Local Government Board. The questions of the origin of the epidemic and of its relation to vaccination are being investigated for the Royal Commission on Vaccination by Dr. Sidney Coupland of the Middlesex Hospital, who has already been in the district for some weeks.

Welsh Medical Inspectors.

In the House of Commons, on May 3rd, in answer to Mr. G. O. Morgan, Mr. Long said it was stated by the President of the Local Government Board, in reply to a question a short time since, that in the event of his having to fill up a vacancy in the office of medical inspector, where the duties of the officer would chiefly be in Wales, and he had before him two candidates who, apart from the question of the Welsh language, were in all respects equally well qualified for the position, he would be willing to give the preference to the candidate with a knowledge of the Welsh language. I cannot give any further undertaking on behalf of the President of the Local Government Board.

The Public Health Amendment Act.

On May 4th, in answer to Mr. J. M'Carthy, Mr. Jackson said: The regulations relating to the Public Health Amendment Act, 1890, were duly prepared by the Irish Local Government Board and laid before Parliament in accordance with the Act.

Medical Officers in the Navy.

In answer to Dr. Tanner, Lord G. Hamilton said: A certain number of surgeons of the Royal Navy, after returning from service afloat, are now permitted annually to attend metropolitan hospitals for a time on full pay, and the experiment has been attended by satisfactory results.—Dr. Farquharson asked whether the same privilege would be extended to the medical officers in the Army Medical Department.—Mr. Brodrick: I must ask for notice of that question.

Army Medical Staff.

On Thursday in the House of Commons Dr. Tanner asked the Secretary of State for War whether any steps would be taken to remove the disability under which officers in the Army Medical Department suffer as regards precedence at mess; and whether such disability was always in existence, or when instituted.—Mr. Brodrick, who replied, said that medical officers suffered no disability as regards precedence at mess. At their own mess they took precedence according to rank. At other messes they were honorary members, and like other honorary members had no precedence under the rules of the service.—Dr. Tanner asked the hon. gentleman whether his attention had not been called to the correspondence on this subject which had taken place in the medical journals.—Mr. Brodrick replied that he had not seen the correspondence.—Dr. Tanner recommended him to read it.

The Hampstead Disaster.

In reply to a question by Mr. Brodie Hoare, Sir M. Hicks Beach said that he had not yet received the inspector's report on the Hampstead Heath accident, but he had been in communication with the company, and was informed that, although the plan had not been actually decided upon, such structural alterations would be made and increased means of access to the platforms provided before Whitsuntide as would, it was hoped, together with other means taken by the company, remove all risk of further misfortune.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ADAMS, J. D., M.D. St. And., M.R.C.S., has been reappointed Medical Officer of Health for the Yeovil Rural Sanitary District.

ANDERSON, WM., M.B., C.M. Glasg., has been appointed Resident Assistant Medical Officer of the Aberdeen Infirmary.

ARCHER, H. R., M.D. Lond., L.R.C.P., has been reappointed Medical Officer for the First Sanitary District of the Royston Union.

BAINES, J. C., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Malvern Sanitary District of the Upton-upon-Severn Union, vice Weir.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

ADVERTISEMENTS OF CHANGE OF RESIDENCE.

A PRACTITIONER advertises in the *Hull Daily News* a temporary change of residence. Such public notices are not called for. It is the custom to be satisfied with an announcement on the old premises of the new address.

Mr. Chas. R. Christie.—We believe the appliances in question to be quack productions, which certainly have never received favourable notice in the columns of THE LANCET.

Mrs. M. Dudley.—There are several such practitioners in the Medical Register, to which we must refer our correspondent.

PAPILLARY PERITONITIS.

To the Editors of THE LANCET.

SIRS,—Would any of your readers be kind enough to give me a few hints in regard to the treatment of papillary peritonitis in a girl aged fourteen? Is an operation of any use? I should feel greatly obliged if anyone having had experience in such cases would reply.

I am, Sirs, yours faithfully,

May, 1892. PENSNETT.

INFLUENZA.

THE following passage from a letter of Lord Chesterfield's, dated July 9th, 1767, is quoted in *Notes and Queries* of April 30th, 1892:—

"You say that Dresden is very sickly. I am sure London is at least as sickly now, for there reigns an epidemical distemper called by the genteel name of *l'influenza*. It is a little fever, which scarcely anybody dies of, and it generally goes off with a little looseness. I have escaped it, I believe, by being here [Blackheath]."

THE SCOTTISH UNIVERSITIES COMMISSION.

A DEPUTATION of representatives of the various medical schools and other educational bodies in Scotland was received by Mr. Balfour at the House of Commons on Wednesday last. The object of the deputation was to procure, if possible, the reconsideration of the ordinances issued by the Scottish Universities Commission, which become final on the 12th and 18th of this month unless Her Majesty should withhold her consent. Representatives of the General Council of the Universities of Glasgow and Edinburgh, of St. Mungo's and Anderson's Colleges, of the Royal Colleges of Physicians and Surgeons of Edinburgh, and of the Reform Association; representatives in all of twelve educational bodies attended. Mr. Balfour however, refused in the meantime to consider the requisition of the deputation, on the ground that Parliament would be taking too great a responsibility upon itself if, after having entrusted the Commission with considerable administrative powers, it should then take upon itself to reject the ordinances which it had framed. The opposition to the ordinances will, we are informed, be pushed forward in Parliament, and it is understood that a motion will be brought forward in the House of Commons on Monday night, asking Her Majesty to withhold her consent from the ordinances.

Dr. R. H. Bakewell.—The subject of leprosy will soon be brought prominently before the medical profession, when we hope to deal with the point mentioned by our correspondent.

Cyclops.—We should hope that our correspondent's account is imperfect or incorrect. A lawyer should be consulted.

M.D. has not enclosed his card.

BACTERIA IN ACUTE RHEUMATISM.

To the Editors of THE LANCET.

SIRS,—Some time ago I sent you a notice of a bacillus which I had met with in certain cases of acute gout. While making further observations in reference to this matter, I have examined the blood in a number of cases of acute rheumatism, and I have found almost invariably that in acute rheumatism the blood is charged with bacteria in the form of minute cocci to a point which might almost be called saturation. These cocci are easily to be seen after floating the cover-glass upon which the blood is taken, for a period of not less than four hours, in a warm solution of methylene blue. I have examined the Indices of THE LANCET and *British Medical Journal* for the past five years, but can find no record of any similar observation. I should be glad to learn if any bacteriological work has been done in reference to acute rheumatism. Dr. Maclagan, in a recent article, assumed the presence of an organism, but did not state if he had actually demonstrated the same. The cocci are exceedingly small, and require a magnification of 1000 diameters to render them at all visible, which is equal to one-twelfth oil immersion with a No. 8 compensating eyepiece. With this power they are just visible, and exhibit a strong disposition to arrange themselves in chains.

I am, Sirs, yours faithfully,

Putney, May 2nd, 1892. EDWD. F. GRÜN.

*** Dr. Mantle of Halifax read a paper at the British Medical Association, at the meeting held in Dublin, on the Etiology of Rheumatism considered from a bacterial point of view. He also published an article in 1885 on Rheumatism with Infectious Sore-throat.—ED. L.

AN AUSTRALIAN ADVERTISER.

"DR. WM. LANGSTON, *M.R.C.S. Eng.*, 121, Collins-street, Melbourne," advertises both his portrait and his great therapeutical powers in all the ordinary newspaper set of discreditable diseases. Has not the Royal College of Surgeons the power to deal with such a member on the score of his advertisements? Be this as it may, he has been fined £20 for putting M.D. on his plate, he being registered only as "M.R.C.S."

Janus.—There are lunatic asylums in various parts of the world under the English Government. We would advise our correspondent to make application direct to the Under Secretary of State for the Colonies, Downing-street, S.W., for information as to appointments &c.

"TREPHINING FOR EPILEPSY."

To the Editors of THE LANCET.

SIRS,—*Apropos* of an annotation in your issue of to-day's date upon trephining for epilepsy, allow me to mention a case I had in my practice six years ago.

A boy twelve years of age was brought to me suffering from "fits." He had been struck with a stone on the forehead four years previously. I found on examination something hard, but movable, under the cicatrix on the forehead. The mother informed me that previously to his "fits" there was a sharp pain felt in the spot. I had him admitted to our cottage hospital, and then, on cutting down upon the hard substance, found a piece of slate firmly embedded in the tissues. This I removed by excising the surrounding tissues widely. The boy was under observation for twelve months, during which time there were no further attacks.

I am, Sirs, yours faithfully,

Hawick, N.B., April 30th, 1892. JOHN R. HAMILTON, M.D.

NEWSPAPER PUFFS OF MEDICAL MEN.

THE blending of domestic history and professional achievement in the following paragraph from *Truth* is very characteristic of the newspaper puff. We have the best reason for knowing that the subject of it disapproves of it as much as any of our readers can do.

> "Mr. Dormer, who was so seriously injured some three weeks back whilst riding the Duke of Hamilton's mare Miss Chippendale at Sandown Park, has made a most miraculously rapid recovery, and is, happily, now almost himself again. The operation of removing one of Mr. Dormer's eyes was performed by Dr. Higgins, who has come very much to the front in recent years. Dr. Higgins married some years ago Miss Greenwood, a niece of Mrs. John Towneley."

Mr. J. Weller.—Our sources of information were the *Essex Telegraph* and the *Essex Standard*, the names of which were given in the paragraph of which our correspondent complains. We may again point out that we did not impute blame to Mr. Weller, whose disclaimer we gladly inserted, but to injudicious friends, who no doubt imagined that laudatory paragraphs in the lay press are of service to medical men, little recking that but harm can come of such a mistaken procedure.

Mr. A. E. Huxtable, M.R.C.S., is thanked for his communication. We think, however, the newspaper paragraph unworthy of notice.

Argus.—Yes. Messrs. Eyre and Spottiswoode.

PUBLIC VACCINATORS AND BOARDS OF GUARDIANS.

To the Editors of THE LANCET.

SIRS,—Having seen in THE LANCET of April 30th (p. 991) an account of the behaviour of the Watford Board of Guardians towards a public vaccinator, I thought my experience in a similar case might be of interest to your readers, as it differs in the treatment received.

I reported two cases to the Tisbury Board of Guardians last Thursday where the mothers refused to allow me to take any lymph from the children's arms. The guardians without any hesitation said they would take notice of the cases, and instructed the clerk to prosecute, the summons to be heard at the next sitting of magistrates, which is Thursday, May 5th.—I am, Sirs, yours faithfully,

GEO. P. LONGMAN,
Public Vaccinator, Donhead District,
May 2nd, 1892. Tisbury Union.

ANTI-VACCINATIONISTS AT GUILDFORD.

THE defeated anti-vaccinationists of Guildford are losing their temper, as they are evidently losing the game. The reappearance of small-pox in the country, and the forebodings that in public opinion and in the estimation of the Royal Commission the protective power of vaccination holds its unique ground, explain this mood, though they do not excuse it. A writer in the *Surrey Advertiser* calls the Commission a packed Commission, and says guardians ought to—not administer the law of the country, but "carry out the views of those that elect them." Government by boards of guardians is a truly imperial idea. But even so, in Guildford common-sense seems to prevail.

Dolores Fleischmann.—We do not know the work in question.

THE TREATMENT OF DIABETES.

To the Editors of THE LANCET.

SIRS,—A daughter of mine, aged twenty-five, who previously had enjoyed robust health, about six months ago showed signs of diabetes. The usual treatment of codeia with nux vomica and the gluten bread speedily reduced the sugar. But although the usual diet is still strictly enforced, the sugar has reappeared, the specific gravity of the urine having risen from 1019 to 1036. Her weight has, however, not decreased since the disease was first noticed. No member of the family has been known to suffer from the disease previously. Can any of your numerous correspondents suggest any further treatment?

I remain, Sirs, yours truly,

Surrey-square, S.E., May 3rd, 1892. W. RUMBOLL, M.R.C.S., L.S.A.

ALLEGED SCARCITY OF MEDICAL MEN IN NEW ZEALAND.

IT is reassuring to read that there is one place where there is not an excess of medical practitioners. It is said that in spite of a guarantee of £100 by the Government, and of £200 additional by the settlers in the east coast district of the North Island of New Zealand, a qualified man cannot be found. The climate, too, is said to be pleasant. All the same, we should not advise a rush thither without further inquiry.

A DISCLAIMER.

To the Editors of THE LANCET.

SIRS,—I have this morning had my attention called to a paragraph in your issue of the 30th ult. on "Advertising through Hospitals," and at once write to disclaim all responsibility in the matter. The advertisement referred to was ordered to be inserted by the secretary of the hospital without any previous intimation to or consultation with me.

I am, Sirs, yours faithfully,

Birmingham, May 3rd, 1892. F. MARSH.

RESIGNATION OF THE BEDELL OF THE ROYAL COLLEGE OF PHYSICIANS.

WITH the resignation of Mr. Gurner of his appointment of bedell of the Royal College of Physicians a familiar landmark of the College passes away. Mr. Gurner has served the College during a period of twenty years, and he is therefore well known alike to Fellows, Members, and Licentiates of the College. The office of bedell carries with it certain grave responsibilities, as may be inferred from the fact that he is required to provide heavy securities for his faithful care of all the property and goods and chattels of the College entrusted to him. He has to issue all notices and summonses relating to the various meetings of the College, and to act as secretary under the direction of the registrar. At meetings of the College he has to carry the mace, and he has to be in attendance at all lectures delivered in the College. He also has authority over the entire household, and has to direct, superintend, and be responsible for the proper performance of the several duties of each member of the household. These manifold duties Mr. Gurner has fulfilled with such regularity that his resignation will cause a blank in the meetings of the College. It is to be hoped that the Finance Committee, to whom the question of a pension has been referred, may see their way so to recognise Mr. Gurner's services as to place him beyond anxiety in his advancing years.

Senator.—A select committee of the Cape House of Assembly was appointed on July 25th, 1883, "To inquire into and report upon the spread of leprosy at the Cape." A Leprosy Repression Act was passed by the Cape House of Assembly in 1884.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Sir James Crichton-Browne; Messrs. Blondeau et Cie., London; Dr. Fletcher Beach; Messrs. Broatch and Hall, Keswick; Messrs. J. Ball and Sons; Mr. Benedict, Chelsea; Dr. Barnard, Alderney; Messrs. Barker and Son; Mr. Birchall, Liverpool; Mr. T. Bell, Lancaster; Messrs. Cox and Co., Brighton; Dr. C. P. SOLUBLE "TABLOIDS" OF COMPRESSED DRUGS.

"PURE, PORTABLE, PERMANENT, AND PALATABLE" DRUGS.

The real secret of our success has been in gaining the full confidence of the profession by absolute purity and reliability of every product we issue, and then in placing these pure products before them in the most active, pleasing, and acceptable forms. Our earnest efforts in perfecting our "PURE, PORTABLE, PERMANENT, and PALATABLE" products have brought us liberal reward, and we have no doubt just as rich a reward may be gained by others who will try by original work and real merit to win confidence instead of of branding themselves as pirates by resorting to questionable practices.

The "Tabloids" of Compressed Drugs in accurately divided doses, greatly lessen the risk of error by nurses and patients, and afford an unchangeable and acceptable form for administration.

Pure drugs are always cheapest in the end. Those who deceive by imitating labels and packages are also capable ubstituting impure drugs.

HYPODERMIC "TABLOIDS" (prepared by BURROUGHS, WELLCOME, & CO.).

The Hypodermic "Tabloids" are soluble, of uniform activity, and keep perfectly. In solution, whether prepared with an antiseptic or not, most of the active principles quickly undergo change. All the alkaloids and glucosides are perfectly preserved in the "Tabloids," and may be quickly dissolved as required.

THE LANCET reports that "*they are readily soluble, and not at all irritating.*" They present the advantages that the dose is always accurate, the active principle unchangeable, and that they are compact and perfectly soluble.

New formulæ are being constantly added to the list.

Put up in tubes, each containing 20 "Tabloids," at 12s. per dozen tubes, with the exception of Nos. 1, 7, 20, 21, 31, 32, 33, 40, 41, 42, 43, 48, 53, 54, and 56, which contain 12 "Tabloids."

B., W., & CO. HYPODERMIC "TABLOID" POCKET CASES.

Equipped with a No. 7 B., W., & Co. Hypodermic "Tabloid" Pocket Case (15s.), the Physician has a more complete armamentarium for procedure in emergencies than is elsewhere procurable. This is the most complete and convenient Hypodermic "Tabloid" Pocket Case ever introduced, and has been adopted by the leading physicians throughout the world, and is used on the principal steamships under requirement of the new medical regulations of the Board of Trade.

No 7 (B., W., & Co.) Hypodermic "Tabloid" Pocket Case, arranged to *contain* 12 Tubes of the HYPODERMIC "TABLOIDS," Hypodermic Syringe, with 2 Needles, and Mortar and Pestle for crushing the "Tabloids," 5s. each to the Profession.

The same Case, *fitted complete*, and fitted with 12 Tubes of the Hypodermic "Tabloids," selected from the list, 15s. each to the Profession.

"TABLOIDS" OF COCAINE.

We have long made a very special feature of Cocaine, and enjoy exceptional facilities for supplying a superior product at moderate prices. The insoluble products of the market have, from time to time, caused inconvenience to the profession, and the disappointing results sometimes obtained were partly due to unreliable preparations of the drug and partly to their having undergone a change in solution.

The "Tabloids" of Cocaine dissolve almost instantaneously and remove all possibilities of disappointment, for the Cocaine in them is the purest, the most active, and most reliable manufactured. They constitute the best and most convenient form for hypodermic medication or for the preparation of solutions. Furthermore, they present the advantages that the dose is always accurate and the active principle unchangeable.

"Tabloids" of Cocaine are supplied to the Profession in Bottles of 25 at 2s. 6d. each.

LIST OF "TABLOIDS" PREPARED BY BURROUGHS, WELLCOME, & CO.

Aconite Tinct., 1 min.
Aloin, 1-10 gr.
Ammon. Bromide, 5 and 10 gr.
Ammon. Chloride, 3, 5, and 10 gr.
Ammon. Chloride with Borax.
Antacid (*Soda Bicarb., Potass. Bicarb., Magnes. Carb., aa 2 gr. & Sodii Chlorid., 3 gr.*)
*Anti-Constipation (*Aloin, 1-5 gr.; Belladonna Ext., 1-8 gr.; Strych., 1-60 gr.; Ipecac., 1-16 gr.*)
Antifebrin, 2 gr.
Antimony Tartrate, 1-50 gr.
Antipyrin, 5 gr.
Apomorphine Mur., 1-50 gr.
Arsenious Acid, 1-100 and 1-50 gr.
Atropine Sulph., 1-100 gr.
Belladonna Tinct., 1 min.
Bismuth Subnitrate, 5 and 10 gr.
Blue Pill, 3 gr.
Borax, 5 gr.
Caffeine Citrate, 2 gr.
*Calcium Sulph., 1-10 gr.
Calomel, 1-10, ½, and 1 gr.
Capsicum Tinct., 1 min.
*Cascara Sagrada Ext., 2 gr.
*Cascara Comp. (*Cascara Dry Ext., 1 gr.; Euonymin, ¼ gr.; Nux Vomica Ext., 1-16 gr.; Hyoscyamus Dry Ext., 1-3 gr.*)
*Cathartic Comp., U. S. P. (*Ext. Coloc. Co. Pulv., 1 1-3 gr.; Ext. Jalapæ Pulv., 1 gr.; Hyd. Subchlor., 1 gr.; Cambogiæ Pulv., ½ gr.*)
Charcoal, 5 gr.
Chloralamid., 5 gr.
Chloral Hydrate, 5 and 10 gr.
Cocaine Mur., 1 gr. (Voice).
Cocaine with Potash and Borax
Cretæ Aromat. cum Opio Pulv., 5 gr. (Aromatic Confection with Opium.)
Dialysed Iron, 10 min.
Digitalis Tinct., 1 min.
Digitalin, 1-100 gr.
Diuretin-"Knoll," 5 gr.
Dover Powder, ½ and 5 gr.
Euonymin Resin, 1-8 gr.
Exalgin, 2 gr.
Ferrum Redactum, 2 gr.
Gregory Powder (see Rhubarb Comp. Pulv.).
Hydrarg. cum cretâ, 1-3, ½, and 1 gr.
Hydrarg. Iod. Rub., 1-20 gr.
Hydrarg. Iod. Vir., 1-8 gr.
Hydrarg. Perchlor., 1-100 gr.
Hydrarg. Subchlor. (Calomel), 1-10, ½, and 1 gr.
*Hydrastis Comp. (*Hydrastis Mur., ½ gr.; Ergotin, ½ gr.; Cannabin Tannate, ½ gr.*)
Ichthyol, 2½ gr. (Powder).
Ipecac. and Opium, 5 gr. (Dover
Ipecac. Powder, 1-10 and 5 gr.
Iron and Arsenic Comp. (*Quinine Bisulph., 1 gr.; Iron Hypophosp., 2 gr.; Arsenic, Strychnine Sulph., aa 1-50 gr.*)
Iron and Quinine Cit., 3 gr.
*Laxative Vegetable (*Res. Podoph., Ext. Hyosc., Ext. Taraxac., aa 1-4 gr.; Ext. Coloc. Pulv., 1 gr.; Jalapæ Pulv., Res. Leptand., aa 1-2 gr. Ol. Menth. Pip.*)
Lithia Carbonate, 2 gr.
Lithia Co. (Dr. Lane's formula).
Manganese Dioxide, 2 gr.
Morphia Sulph., 1-100, 1-20, and 1-8 gr.
Naso-pharyngeal (*Sodium Chlorid., Borax, Boric Acid, Benzoic Acid, Menthol, Thymol, Ol. Gaultheriæ, Cocaine Mur.*)
Nitro-glycerine, 1-100 gr. (see also Trinitrine).
Nux Vomica Tinct., 1 min.
Opium Tinct. (Laudanum), 2 min.
Papain, 2 gr. (Dr. Finkler & Co.)
Pepsin (Fairchild).
Pepsin, Saccharated, 5 gr.
Peptonic (*Pepsin, Zymine, Lactophosph. Lime, p. æq.*)
Phenacetin, 5 gr.
Pilocarpin Mur., 1-20 gr.
Podophyllin Resin, ¼ gr.
Potass Bicarb., 5 gr.
Potass Bromide, 5 and 10 gr.
Potass Chlorate, 5 gr.
Potass Chlorate with Borax.
Potass Iodide, 5 gr.
Potass Nit. (Sal Prunella), 5 gr.
Potass Permanganate, 1 and 2 gr
Quinine, 1-10 and ¼ gr.
*Quinine (Soluble), 1, 2, 3, and 5 gr.
Reduced Iron, 2 gr.
Rhubarb, 3 gr.
*Rhubarb Comp. (Pill), 3 gr. (*Rhei. Pulv. 1½; Aloe Soc. Pulv., 1; Saponis Pulv., 5-8; Myrrhæ Pulv., 5-8 parts; Ol. Menth. Pip.*)
Rhubarb Comp. Pulv. (Gregory Powd.), 5 gr.
Rhubarb and Soda, 5 gr. (*Rhei., 3; Sodæ Bicarb., 2; Zingiber, ½ parts.*)
Saccharin, ¼ gr.
Salicin, 5 gr.
Salol, 5 gr.
Santonin, ¼ gr.
Soda Bicarbonate, 5 gr.
Soda-Mint, or Neutralising "Tabloids" (*Soda Bicarb., 4 gr.; Ammon. Carb., ½ gr.; Ol. Menth. Pip., ½ gr.*)
Soda Salicylate, 3 and 5 gr.
Strophanthus (2 minims of Tinct. in each).
Sulphur Comp. (*Sulph. Præcip., 5 gr.; Potass. Bitart., 1 gr.*)
Tannin, 2½ gr.
Test Tabloids (Fehling's).
Thirst (Effervescent).
Tonic Comp. (*Iron Pyrophos., 2 gr. Quinine Bisulph., 1 gr.; Strychnine Sulph., 1-100 gr.*) (and 1-50 gr.
Trinitrine (Nitro-glycerine), 1-100
Trinitrine and Amyl Nitrite.
Trinitrine Comp. (*Trinitrine, 1-100 gr.; Nitrite of Amyl, ½ gr.; Capsicum, 1-50 gr.; Menthol, 1-50 gr.*)
Urethane, 5 gr.
Voice (Potash, Borax, & Cocaine).
Warburg Tincture, 20 min. in each.
Zinc Sulphate, 1 gr.
Zinc Sulpho-carbolate, 2 gr.
Zymine (Pancreatin).
Zymine Comp. "Tabloids" (*Zymine, 2 gr.; Bismuth Subnit., 2 gr.; Powd. Ipecac., 1-10 gr.*)

Those "Tabloids" marked with an asterisk are coated with a perfectly soluble coating of pure white sugar. These coated "Tabloids" WILL ONLY BE DISPENSED BY CHEMISTS WHEN SPECIALLY INDICATED BY THE PHYSICIAN.

BURROUGHS, WELLCOME, & CO., SNOW HILL BUILDINGS, LONDON, E.C.,
Will be happy to send Price Lists and Samples of Soluble "TABLOIDS" to Medical Men post free on request.

A BOON TO DYSPEPTICS.

Bynin — LIQUID MALT.

This liquid preparation of **Malt Extract,** so favourably known to the medical profession for many years, while possessing all the digestive and nutritive powers of the ordinary thick extract, is so much pleasanter to handle, and easier to take, that by many persons it is infinitely preferred to the older form. The activity of the Diastase upon which the value of Malt Extract chiefly depends is very pronounced—in fact, it is greater than in the thick extract, owing to the fact that it has been subjected to heat for a shorter time. In addition to Diastase, Maltose and Dextrine are largely present, together with Phosphates and a certain amount of Nitrogenous material, all possessing considerable value as articles of diet.

CHIEF USES.—Malt Extract has been most largely prescribed in wasting diseases, and its use has been almost invariably followed by very good results, emaciation being stopped and the patient putting on flesh. It is most probable that this result is due partly to improved digestion, from the assistance given by the malt diastase to the diastase of the Salivary and Pancreatic Juices, and partly to the fact of Nitrogenous tissue-waste being saved by the Carbohydrates.

The presence of diastase clearly points to the use of Bynin in certain forms of dyspepsia due to weak digestion, and in such cases the practical experience of many medical men has abundantly proved the great value of this preparation.

For **Children** Bynin is especially useful, as its pleasant taste renders it very palatable, and digestive disorders being the commonest found amongst children, such a powerful aid to digestion and nutrition cannot fail to be of the utmost service. On this point we have abundant testimony of the most varied description.

For **Women** whilst suckling, Bynin has been given in milk, in place of Stout or Porter, with the best results, forming, as it does, a highly nutritive and easily digested food, which increases the flow and enriches the quality of the milk; and, what is of great importance, renders it more assimilable and easy of digestion by the infant.

METHOD OF ADMINISTRATION.—The *best* way to take Bynin is *during the meal.* It may be sipped slowly either by itself, or mixed with water, wine, milk, lemonade, &c., or may be taken stirred up with gruel or farinaceous puddings. It is better taken in this way than after the meal, when its action is much hampered by the acid secretion of the stomach. Nursing mothers should take one tablespoonful, in half a tumbler of new milk, three times a day *between* meals.

☞ **One FLUID ounce of Bynin represents one ounce by WEIGHT of Allen & Hanburys' ordinary thick MALT EXTRACT, which is sold in wide-mouthed jars, similar to their Bynol jars, at (retail) 1s. 6d. and 2s. 9d. each.**

THE LANCET writes: "We find that one ounce of Bynin will digest perfectly one pound of starch. This is a most favourable result, and, coupled with the fluidity and pleasant flavour, renders this preparation a most valuable one."

In Bottles at (Retail) 1s. 9d. and 3s. each; 16s. and 27s. per dozen to the Profession.

Lecture
ON
THE CONCENTRATION OF POPULATION IN CITIES.

Delivered at University College, London, on Feb. 24th, 1892.

BY G. V. POORE, M.D., F.R.C.P.,

GENTLEMEN,—The steadily increasing tendency of population to leave the country and concentrate in towns is a fact which does not admit of a doubt. Of the twenty-nine millions of inhabitants of England and Wales, about 18,500,000 are classified by the Registrar-General as belonging to town districts and about 10,500,000 as belonging to country districts. In 1801 London contained about one-eleventh of the entire population of England and Wales, whereas according to the last census it was found to contain about one-seventh of the entire population. Dr. Gould of Washington, in a paper read before the late International Congress of Hygiene and Demography, stated that a short half century ago the urban population of the United States was 3·5 per cent. of the whole, while to-day the urban population constitutes 29 per cent. of the whole. The American city, says Dr. Gould, "creates itself with appalling suddenness," and it is probable that Chicago, with its 1,200,000 inhabitants, having doubled its population in the last ten years, may be said in this particular matter to have beaten the record. It must not be forgotten, however, that London has more than doubled its population in the last half century; that Cardiff has risen from 80,000 to 130,000 inhabitants in the last ten years; that Barrow-in-Furness, Eastbourne, Bournemouth, West Ham, and Croydon are all instances of towns (and other instances could easily be given) which have sprung into existence within the memory of many of those whom I am addressing. It is important to bear these facts in mind, as showing that the English cities, equally with those in America, create themselves with appalling suddenness; that we do not merely inherit our cities with their various shortcomings, but that we create them for ourselves, and are directly and solely answerable for their good or ill construction. The cause of this concentration of population is the desire for business, the wish to get money easily and quickly, and to spend it advantageously. A man who trades in a centre of express mail services, telegraphs, and telephones, has all the world before him if he knows how to make use of it. There is consequently a rush for such favoured centres, and it has come about that steam and electricity, which annihilate time and space, instead of enabling us to live further apart from each other, have produced a directly opposite effect. The dealer, be he wholesale or retail, likes to be surrounded by a crowd of potential customers, rather than be dependent on a few; and the artisan naturally turns to great industrial centres as offering the readiest market for his labour, and often finds out too late that the higher wages of the town are more than counterbalanced by the extra cost of living. The crowds of independent and idle persons who settle in the towns do so because they find a greater variety of methods of killing time, or, as they prefer to put it, because the state of civilisation is greater in the towns than in the country. But what is civilisation? A recent anonymous writer (the author of "Behind the Bungalow") speaks of this "half hatched civilisation of ours, which merely distracts our energies by multiplying our needs, and leaves us no better off than we were before we discovered them"; and we must all admit that there is a good deal of this kind of civilisation which passes current at the present day, and especially in cities, where a large proportion of the population are the slaves of inane conventionalities. Cities are the abodes of art, and art in all its forms is elevating; but it is a question whether the increasing difficulties which, especially in London, we encounter in the study and appreciation of nature, do not more than counterbalance the artistic advantages of the town. "Pictures, taste, Shakespeare, and the musical glasses" are not the only things worthy the attention of civilised man, and it is noteworthy that many of the leading spirits in all ages have turned from the artificial enjoyments of the town to the greater freedom and more natural pleasures of the country. It is said that our rural fellow subjects, having been forcibly educated to a pitch which enables them to study all the gay doings of the town, are beginning to find the country insufferably dull. The cause of dulness, however, is in ourselves and not in our surroundings. Our country friends must be taught that they have at hand one of the surest cures for dulness. Let them learn to study and appreciate the book of nature—that book which is always with us, ever open and inexhaustible—and dulness will become impossible.

The mind which has occupation to really interest it cannot be dull or weary, and the surest way to find interest in this life is productive labour. In the making of a pudding, the raising of crops, the writing of books, the practice of a profession, and in all the constructive arts, it is necessary to use the judgment; and it is this exercise of judgment which is the true complement of book-learning. The man who reads and who produces nothing is seldom capable of action, he becomes giddy with the opinions of others, and finds it impossible to have a fixed opinion of his own. In action and production the mere see-saw of criticism is of no use, we must make up our minds. We must really think, and the man who has learnt to think runs little risk of being dull. Those who have to cope with the uncertainties of nature are bound to exercise their judgment in a high degree. Unless the farmer be constantly thinking and looking ahead, and unless he bring (often unconsciously) a good deal of science to bear upon his practical work, he will have no chance of success. We are not to sit in judgment on such a one because he does not show the alacrity, sharpness, and power of repartee which are seen in the town dweller. The cockney and the yokel are educated in totally different schools, neither understands the other, and they have for each other a good deal of mutual contempt. It is difficult, however, to believe that he who can perform the varied duties of the farm, and who has been brought up in contact with a wide range of natural phenomena, is not the equal intellectually of the factory hand, who is the slave of a machine which thunders to and fro with brutal accuracy for ten hours at a stretch. Physically the country labourer is vastly superior to the town dweller, and be it remembered that mental power is mainly dependent on physical health.

One of the undoubted consequences of the concentration of population in towns is deterioration in physical health. The disease-rate and the death-rate are both higher in urban than in country districts. The difficulties of rearing children are much greater in towns than in the country, and the risk of faulty development in those which are reared is also greater. The undue concentration of population must tend towards the deterioration of our race, and there can be no doubt that the diminution of the evils of such concentration is a subject which demands very earnest attention. We all of us have to run more or less risk in earning our living. Some enter the army or navy, some go to tropical countries, some become file-grinders, hotel servants, or doctors, and it is not, perhaps, desirable that the bread-winners should look too narrowly at the risks connected with their daily work. Every prudent man, however, will endeavour to secure vigorous health for his wife and children; and, whenever it can be avoided, these should not be called upon to run unnecessary risks.

The Registrar-General's returns show that for every 100 deaths in country districts there are about 120 deaths in towns, and that the death-rate of children under five, per 1000 living at that age was (in the year 1890) 66·5 in Lancashire and 65·2 in London, as against 30·3 in Dorsetshire, 31·1 in Wiltshire, 31·8 in Berkshire, 31·2 in Rutlandshire, 35·8 in Herefordshire, 35·3 in Shropshire, 35·8 in Hampshire, 36·4 in Oxfordshire, 37·5 in Bedfordshire, 36·0 in Sussex, and 39·3 in Somersetshire; and, although the infant mortality was higher in the other counties having a more urban character, in none of them (except Lancashire and London) did it exceed 57·5. It is thus evident that the risk to children under five is twice as great in London and Lancashire as it is in some of the rural districts. How many children are crippled for life by infantile diseases contracted in towns we have no means of knowing. Death-rates are nowadays the subject of perennial paragraphs in the newspapers, and they are systematically used for puffing localities, and are beginning to form a recognised feature in auctioneers' advertisements.

Before accepting the death-rate as evidence of the healthiness of a locality we must take several facts into consideration. 1. The mobility of the population in the present day is greater than it ever has been previously, and this must have a vitiating effect upon the value of the death-rate, for it is evident to all of us that a man who has contracted a fatal disease, let us say, in London may die at Croydon, Brighton, the Riviera, Cairo, or elsewhere. This fact must largely lessen the trustworthiness of local death-rates, although it does not probably appreciably affect the trustworthiness of the death-rate for the country as a whole. 2. Again, the death-rate of a city is of little value unless correction be made for abnormal age distribution. London, especially the central parts of it, contains a great deficiency of persons at the extreme (and most vulnerable) periods of life, and this of course helps to keep the death-rate lower than it would be if it contained its due proportion of tender infants and feeble old persons. The population of central London, it must be remembered, is largely composed of selected adults imported from the country. 3. Lastly, let me say that the death-rate of London is kept down very largely by a process of dilution. If any comparison is to be made between the London of to-day and the London of former times, we must be careful to select identical areas. As it is, the high death-rate of the centre is diluted by the low death-rates of the outskirts, and the healthiness of Hampstead, Lewisham, and other outlying districts is used to conceal the condition of the centre.

For the sake of my argument I have divided the population of London into three portions as nearly equal as the very irregular shape of the registration districts will permit.

1. The outer portion, consisting of the outlying districts of Hammersmith, Fulham, Hampstead, Islington, Hackney, Poplar, Battersea, Wandsworth, Camberwell, Lewisham, and Plumstead, and containing 1,676,475 inhabitants according to the last census.

2. Districts holding a middle position—viz., Kensington, Chelsea, Paddington, St. George's (Hanover-square), Marylebone, St. Pancras, Lambeth, Greenwich, and Woolwich, and containing a population of 1,317,078 inhabitants.

3. The central districts, which might be spoken of as London proper. These include, in addition to the "central districts" of the Registrar-General, Westminster, Shoreditch, Bethnal Green, Whitechapel, St. George's-in-the-East, Stepney, Mile-end, Southwark, Newington, Bermondsey, and Rotherhithe. These districts form a compact city in a ring fence, and contain 1,217,503 inhabitants, a population twice as big as that of any other city in the country. I have taken the deaths of the various districts as published in the corrected quarterly tables of the Registrar-General, and from them I have calculated death-rates for these three divisions of London for every quarter during the last two years.

London Population 4,211,056.	1890. 1st Qtr.	1890. 2nd Qtr.	1890. 3rd Qtr.	1890. 4th Qtr.	1891. 1st Qtr.	1891. 2nd Qtr.	1891. 3rd Qtr.	1891. 4th Qtr.
Outlying Districts Population 1,676,475.	20·9	15·4	16·5	21	20·4	20·2	14·1	17·6
Middle Districts Population 1,317,078.	24·3	17·6	17·6	22	24·3	23·3	16·8	19·7
Central Districts Population 1,217,503.	29·6	21	22·9	28·8	28	27·9	20 7	24·9 *

* The deaths in the first quarter of 1892 give death-rates of 25·7, 27·4, and 32·0 for the outer, middle, and central districts respectively.

If we take the yearly rates instead of the quarterly we have the following results:—

	1890.	1891.
Outlying Districts.....	18·4 per 1000	18·1 per 1000
Middle Districts	20·4 ,,	21·0 ,,
Central Districts	25·6 ,,	25·4 ,,

From the above tables it is evident that when we boast of London as a healthy city we must exclude the central districts, or London proper, with its 1,200,000 inhabitants. Indeed, the death-rate of London proper was extremely high in 1890 and 1891, but, large as the figures are, they do not show the full state of the case, because no correction has been made for age distribution and mobility, which is essential before we can compare them with the rates for the rest of the country. Nothing can show better than these figures the effect of overcrowding on death-rate. Not only are the central districts the most crowded and the poorest, but they are hemmed in on every side by the middle and outlying districts, so that fresh air can never reach them. As a result, we find the death-rates are some 40 per cent. higher than the rates for the outlying districts. In all seasons and under all conditions the uniformity of relation between the rates of the outlying and central districts is maintained. If we take the first quarter of 1890 and the second quarter of 1891, during both of which we had an epidemic of influenza, we find that the death-rate of the outlying districts was 20·9 and 20·4, while for the central districts it was 29·6 and 27·9. Or take the last quarter of 1890 and the first quarter of 1891, which were characterised by weather of great severity, we find that in the outlying districts the death-rate was 21 and 20·4, while in the central districts it was 28·8 and 28, notwithstanding the fact that the temperature of the central districts was certainly considerably higher than that of the outlying districts. If we take the periods when the climatic conditions are at their best, the same relationship in the figures is maintained. Thus for the third quarter of the two years the rates of the outlying districts were 16·5 and 14·1, while for the central districts they were 22·9 and 20 7.

Finally, let us take a period when the climatic conditions were at their worst, as during the fog of last Christmas, which commenced on Dec. 21st, and continued for parts of five days. During this fog the mean temperature of the air was 25° F.; the air was calm, with slight easterly currents, and saturated with moisture; ozone and sunshine absent. Under these circumstances the irritating products of combustion and the soot from thousands of chimneys remained suspended in the fog, as did also the effluvia from over 4 000,000 human beings and the varied impurities of a big city. The air was bitterly cold and irritating, and from the absence of wind could not be renewed, so that the citizens of London were very much in the condition of gold fish in a bowl whose water has not been renewed. The corrected average weekly number of deaths for the fortnight ending Jan. 2nd, 1892, was 3728, while the deaths which actually occurred were 5170, so that we have 1442 deaths actually caused by the fog. The death-rate for the whole of London for this fortnight was 32, the figures for the three areas being 29 for the outlying districts, 31·8 for the middle districts, and 38 for the central districts. This high death-rate for the central districts, which are the warmest, seems to show that it is not merely the coldness of the fog which raises the death-rates, but rather the impurities, mechanical, chemical, and infective, which it contains.

Bad as are the health conditions in the centre of London, they are eclipsed by those of New York. In the city of New York, which had a population of 1,600,000 in 1890, more than 1,200,000 of the inhabitants live in tenement houses. The density of population averages 65 persons to the acre, while in many of the wards it is over 200 to the acre, and in one ward it reached 559 persons to the acre. The average death-rate for the past ten years was over 26, and in the year 1890 the deaths exceeded the births by 980, and while there were 39,250 births in the year the authorities are jubilant because only 10,288 of the children born, or rather more than 26 per cent., died before they were a year old. The deaths in New York invariably exceed the births, so that the population is maintained and increased entirely by immigrants. The birth-rate is exceedingly low. Last year it was only 24, and that was a higher figure than had been reached in any of the thirty previous years. It must be remembered that New York has a magnificent water-supply and a very complete system of sewerage. As in London, there is apparently a very great deficiency of very young and very old inhabitants; and, as in London, it may be presumed that a very large number of those who fall ill retire from the city to die elsewhere. Notwithstanding the great activity of the sanitary officers, it is evident that the state of public health in New York is far from good, and that, owing mainly to the density of population, it is not a very wholesome place.

The evils of overcrowding on space have been made more plain and comprehensible by the discoveries which have been made in the new science of bacteriology. When the public hears that a new microbe has been discovered in connexion with this or that disease, it says, "Now, surely, we shall have a cure." It may be well to point out that, hitherto, in no case has the discovery of a microbe led to the discovery of a cure; and the evidence that the study of the life-history of pathogenic microbes is likely to lead to the discovery of "cures" is, to say the least, not very strong. "Prevention," however, "is better than cure"; and it is clear that the study of the life-history of pathogenic microbes must precede all adequate measures for preventing the diseases which they cause.

It was the study of the life-history of the microbes which produce putrefaction which led Sir Joseph Lister to adopt the antiseptic treatment of wounds which has produced such grand results. The knowledge that cholera and typhoid poisons can live in water has led to great caution in the selection and protection of water-supplies, and I believe the time is not far distant when we shall regard the wilful mixing of excremental matters with water as, in a sense, an act of public suicide. Again, the knowledge that typhoid fever, diphtheria, and scarlet fever are often connected with the milk-supply has been the means of arresting many an epidemic. In short, the medical profession has no cause to feel ashamed of its recent progress in the direction of prevention of disease, which, as Sir William Jenner used forcibly to teach in this college, should be the great aim of a physician.

While certain diseases reach us *vid* water and food, there are others which come to us in the air we breathe, and it is well to bear in mind that it is in relation to air-borne diseases that overcrowding is especially dangerous. Whooping-cough, measles, scarlet fever, tubercle, typhus fever, small-pox, influenza, pneumonia, and plague, and, to a less extent typhoid fever, are among the diseases which are air borne, and the spread of which is, in a very obvious way, favoured by overcrowding. It is definitely known with regard to some, and may, I think, be safely inferred with regard to all the above-named diseases, that the carriers of the infection are particulate and alive. A sufferer from any one of these diseases is continually giving off infective particles, and the danger of the infection travelling to a second person depends (1) upon the distance of the second from the first; (2) the ease with which the infected air can be diluted with fresh air. Thus the danger caused by proximity to an infected person in the open air is comparatively slight, because the chance that the infective particles will be blown away by the wind is very great. When, however, the infected and the healthy come to live under the same roof, to occupy the same room, and, still more, the same bed, the risks of infection are enormously increased, because the air in the confined space gets very largely charged with infective particles and the healthy can hardly avoid taking in the infection, and that, too, in large quantities. Given the rate of movement of the air, the degree of proximity of the individuals, and the number of infective particles given off by the diseased person, and the risk of infection could be stated as a mathematical formula. There is good reason to believe, however, that the mere fact of overcrowding produces some change (possibly chemical) which greatly increases the risks of infection, apart from the mathematical factors above alluded to. Some of the facts connected with the recent epidemic of influenza bring out very clearly the increased danger of infection which results from overcrowding between walls and under a common roof.

Overcrowding is seen at its maximum in the forecastle of a ship after the men have "turned in," and the danger to all should any case of infective disease be present among them is well-known. The explosive outbursts of influenza which are liable to occur on board ship have been amongst the startling features of every epidemic. In the same way explosive outbursts of the disease have occurred in establishments where many persons have a common employment under a common roof, as witness the sudden occurrence of a thousand cases at the end of 1889 in the Magazins du Louvre at Paris, and a similar outburst at the General Post Office in January, 1890. A careful consideration of the whole of the facts of the epidemic of 1889-90 leads Dr. Parsons, in his report made to the Local Government Board, to conclude:[1] "8. That in public services and establishments persons employed together in large numbers in enclosed spaces have suffered in larger proportion than those employed few together or in the open air. 9. That in institutions in which the inmates are brought much into association the epidemic has more quickly attained its height, has prevailed more extensively and been sooner over than in those in which the inmates are more secluded from one another." The converse is also true, for Dr. Parsons states that those living away from the possibility of infection and in small groups such as light-house keepers and deep-sea fishermen enjoyed a remarkable immunity from the epidemic. It must be remembered that what is true of influenza is also true of other air-borne infections. It is known that whooping-cough and measles are prevalent and fatal very much in proportion to the density of population on a given area, and it has lately been shown that although the mortality in so-called model dwellings is below that of the working-class dwellings as a whole, the occurrence in them of infantile infectious diseases, including diphtheria, is distinctly above the average. This is not to be wondered at, for with a large number of persons under a common roof the risks of infection must be proportionate to the number of inhabitants.

The modern city is distinctly a modern invention; it had no counterpart in ancient times. The ancients crowded behind walls from fear of their enemies. The modern city has no walls and no need of them, and there does not seem to be the same necessity for overcrowding that there was in the ancient city. As a matter of fact, however, the modern city both here and in America exhibits a degree of overcrowding on space such, as I believe, has never existed in the history of the world. The main cause of the difference between the ancient and modern city is the possession *of water under pressure*. In ancient Rome an excellent supply of water flowed from the neighbouring hills along open aqueducts supported on arches, and it is probable that the greatest head of water to be found in ancient Rome was represented by the height of the aqueducts above the level of the ground. Most of the buildings in ancient Rome were what we should consider low. The dwelling-houses were rarely more than one storey, or at most two storeys, high, and it was only in public buildings—temples, baths, basilicas—that an attempt was made to carry the edifice to any great height. In mediæval cities, three-storeyed buildings represented the average maximum, for without water under pressure very high buildings were impracticable owing to the labour of carrying water to the upper storeys and the difficulty of removing refuse. Formerly a house was scarcely habitable unless it had a courtyard of some kind. This was essential for sanitary purposes—for a well and for the bestowal of refuse pending its removal by the scavenger; most of the decent houses in mediæval London had a considerable amount of curtilage, as may be seen by consulting the maps of Aggas, Rythe, Newcourt, and others. The steam engine and the cast iron water pipe have together created a new order of things. The steam engine gives us any head of water we desire, and the modern iron fittings are able to stand any pressure to which we may find it necessary to subject them. There is no longer any difficulty in taking water to the top storey of any house, however lofty; no longer any difficulty in washing the filth out of any dwelling-house, however big; there is no longer any absolute necessity of limiting the height of buildings; no longer need of any curtilage to a house, nor for any outlet other than a pipe. This, indeed, is magical. "My estate," says one, "has risen in value from £100 an acre to £5 a foot." "My water shares," says another, "pay me 12 per cent." "My mansions in the sky," says the builder, "have sold for double what they cost me." All the gas shareholders and those who have invested in electric supply companies join in the chorus of delight. This is, indeed, a civilising and wonderful age. Let us build a temple, and place in it a steam engine, an iron water pipe, and a hydraulic lift. Under these very money-making conditions it is not to be wondered at that the craze of the present time is for tenement houses, which are called model dwellings, flats, or mansions, according to the class for which they are intended. Whatever they may be called they are all of the same type, and they are calculated to trouble the soul of the sanitarian who knows the danger of overcrowding on space and under a common roof.

Let us hear what Edinburgh can teach us on this subject.

[1] See p. 101 of the Report on the Influenza.

In a very excellent paper on the Hygiene and Demography of Edinburgh, which was communicated to the late Congress, and which is now published in the twelfth volume of the Transactions of the Congress,[2] I find (p. 66) the following passage:—"Edinburgh enjoyed for many years the unenviable notoriety of being subject to periodical outbursts of fever. These assumed in all cases the epidemic form, and entailed a large mortality among the citizens. ..... There can be no doubt that one main cause of these repeated outbreaks was the manner of housing the inhabitants which, copied from the French, consisted in piling tenement above tenement until a large overcrowded population was confined in a limited space, and could only communicate with the outer world by a narrow stair. ..... When infectious disease of any kind broke out in such circumstances, it spread with great rapidity, and quickly assumed the epidemic form." Tenement houses are common in Paris, where the overcrowding on space as a consequence is on an average twice as great as in London, and where the death-rate is considerably higher than in London. (In 1881 I find the death-rate was 28 per 1000 in Paris.) The condition of New York I have already alluded to. It is doubtless gratifying to national vanity to have a capital city composed of huge edifices which may be made to look palatial from the outside, but there is also no doubt that the comparatively low death-rate which London has hitherto enjoyed is to be attributed to the fact that as a rule each family has had a house of its own. It is strange that the craze for high buildings has reached its maximum in America, where cities have sprung into sudden existence on the boundless prairie, where space should be no object. The main causes of this seem to be hurry, avarice, an insane spirit of competition, and the difficulties connected with domestic service in a country where the citizens are more willing to slave for a machine than serve a mistress. Life in hotels and boarding-houses is more common in America than here, and coöperative housekeeping has reached a high stage of development. Water, warmth (by steam coils), gas, electricity, telephones, and hydraulic power are supplied to groups of houses from common centres. This is a convenient arrangement, but one which makes for the overcrowding of houses on space. Domestic architecture is in danger of becoming a lost art in cities where the inhabitants are content to be stored in human warehouses erected by engineers and as full of machinery as a factory. In the most modern city in the world (Chicago), the builders of which have had the opportunity of avoiding all the errors of the past, it is curious to note that the engineer architects have exceeded all previous efforts in the matter of high buildings and disgraceful overcrowding. The "Masonic Temple" in Chicago has twenty storeys and is 265 feet high, and is merely the latest and worst of many similar buildings in the city. In such a city the sewage difficulty is necessarily very great, but we learn that a special canal is to be constructed for its reception, and this is to discharge into the upper waters of the Mississippi! It seems astounding that such an outrage on their noblest river should be tolerated by the American people. The volume of the sewage may be as nothing when compared with the volume of the river into which it is to be discharged, but one would ask, Can this ingenious race, who like to be considered in the van of progress, do nothing better with the sewage of a great city than this? And are we to conclude that their hygiene is founded more on expediency and money getting than on any true scientific, economic, or moral principles? As regards the state of public health in Chicago, I can give a few figures which may help one to form an estimate of it. The following table, compiled from the official mortality returns, shows that for 1890 the death-rate was 18·2, and for 1891 22·2. I have not been able to make any correction for age distribution, but it seems highly probable that Chicago is largely peopled by vigorous adult immigrants who crowd into it in search of employment. The zymotic death-rate was 4·09 in 1890 and 5·61 in 1891, the latter figure being not far from double the zymotic death-rate of London in 1890. The death-rate from typhoid fever was 840 per 1,000,000 in 1890 and 1596 per 1,000,000 in 1891, the latter figure being nearly five times as great as the largest typhoid fever death-rate ever recorded in London. Croup and diphtheria last year killed 1087 per 1,000,000 in Chicago, which is a figure enormously in advance of any that have ever been recorded in London. These figures show with a vengeance that no amount of ingenious engineering can counteract the evils of overcrowding on space.

Death-rate per 1,000,000 living.

—	All causes.	Zymotic.	Diphtheria and croup.	Typhoid fever.	Tubercular affections.	Respiratory affections.	Violence.
Chicago, 1890	18,214	4090	1051	840	1859	3136	1069
Chicago, 1891	22,204	5610	1087	1596	1967	4089	1170
London, 1890	20,978	2896	330	144	2943	4910	719

The following account of Chicago, taken from a paper on the Columbian Exposition read before the Society of Arts in December last by Mr. James Dredge, seems to show that the modern American business city is admirably calculated to rob existence of its pleasures: "No description, in fact, would do justice to this city of 1,200,000 inhabitants, almost every one of whom appears endowed with preternatural activity; which owns a street eighteen miles in length, almost a dead level for the whole distance, and on which are houses twenty storeys high; whose traffic is as noisy as it is ceaseless, both on the smooth-running rope-worked railways and the ill-paved, jolting roads; where the roar of the locomotive and the scream of the lake steamer emphasise the fact that repose and silence are unknown, even in the dead of night; where a pall of smoke, the outpouring of a thousand factories and of ten thousand dwellings, reminds the Englishman of home. Picture all these things, and you can form some idea of Chicago, which has been raised in sixty years by the indomitable energy of Americans, to the rank of the sixth city of the world in point of population ..... Great as Chicago is, the period of her true greatness has yet to come. Its commencement will dawn when her inhabitants give themselves leisure to realise that the object of life is not that of incessant struggle; that the race is not always to the swift, but rather to those who understand the luxury and advantage of repose as well as of sustained effort. Real greatness does not depend on length of streets, nor height of houses, nor even on colossal fortunes; but rather on the wise application and equally wise conservation of energy and intellect. When Chicago ceases to be the city of perpetual haste, and adopts the pace which will be inevitably set for her by time, the names of her great workers will not be erased so early from the book of life, but will be preserved to give their beloved city many more years of really useful work. At present, I think there are no old men in Chicago, because they have no time to grow old; and giving themselves insufficient time for leisure, they have, as a necessary consequence, little opportunity for the higher culture which is born of leisure."

(To be concluded.)

DISSECTING ANEURYSM OF THE THORACIC AND ABDOMINAL AORTA, THE INNOMINATE AND COMMON ILIAC ARTERIES.

BY THOMAS OLIVER, M.A., M.D., F.R.C.P.,
PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

IT is so seldom that one meets with such an excellent illustration of dissecting aneurysm as was furnished by the case subjoined that I venture to crave for it a place in the pages of THE LANCET. We all know the meaning of the term "aneurysm." The prefix "dissecting" is intended to convey information as to the relationship which exists between the blood tumour and the three walls of the vessel. When the innermost layer of a large vessel—say, the aorta—ruptures, blood penetrates into the chink and gradually pushes out the remaining coat or coats of the vessel, according as to whether the rupture has involved the inner two coats or only the innermost lining of that vessel. In dissecting aneurysm, however, it is not so much a localised bulging that occurs as a stripping off or separation of two of the three coats in the wall of the vessel from each other—

Digitized by Google

either the internal from the middle coat, or the external from the middle, or the laminæ of the middle coat from each other; and to such an extent may this stripping off occur, both as regards the transverse and longitudinal axes of the vessel, that the aorta, for example, will seem on section as if it included another bloodvessel within itself. This is what, practically speaking, occurred in my case. The aorta included a smaller aorta within itself, composed of internal and middle layers of the normal wall of that vessel; and this not for one or two inches only, but throughout nearly its whole extent, from the commencement of the descending part of the arch of the aorta, down through the abdominal aorta to a point just above the division of that vessel into the iliac arteries, in which vessels again the dissecting aneurysm reappeared. The same tendency to dissecting aneurysm was present in other parts of the body, so that nearly all the large bloodvessels may be regarded as having been implicated in a morbid process, which was so general as perhaps to raise in the mind of many readers of these notes the probability of the patient having been the subject of aneurysmal diathesis.

J. F——, aged fifty-five, of negro blood, a ship painter, widower, was admitted into the Royal Infirmary of this city on Sept. 2nd, 1890, complaining of shortness of breath and cough, and of ill-defined pains in the chest and back. Beyond the fact that he had syphilis many years ago, there was nothing in his family or personal history that called for remark. It was noted on admission that the superficial veins of the neck were distended, and that the apex beat was an inch below and slightly external to the nipple. There was dulness over the manubrium sterni, and here a peculiar creaking could be felt by the hand on gentle palpation. The pulse was 84; the right radial pulse was feebler than the left. Soft systolic and diastolic murmurs were heard over the mitral area and over the xiphoid cartilage. The softer blowing diastolic murmur was evidently conveyed from the aortic orifice. Over the upper part of the manubrium sterni, particularly towards the left side, there was heard a systolic murmur, which was extremely loud and rough; but to the right of the manubrium sterni, and underneath the first rib, the systolic was followed by a diastolic murmur. A loud rasping systolic murmur was heard in the arteries of the neck. Beyond the respiratory murmur being somewhat coarser than the normal, there was nothing noted in regard to the lungs. On examining the chest posteriorly, there was slight dulness on percussion between the scapulæ. A rough systolic murmur was heard over the supra-scapular area on each side. Over the right supra-scapular area a faint diastolic murmur was detected. This was not present on the left. The left brachial artery pulsated very freely, and rose visibly. There was no pulsation noticed in the right brachial artery. The difference in the pulsation of the right and left radial artery is shown in the sphygmograms. Beyond the presence of an occasional

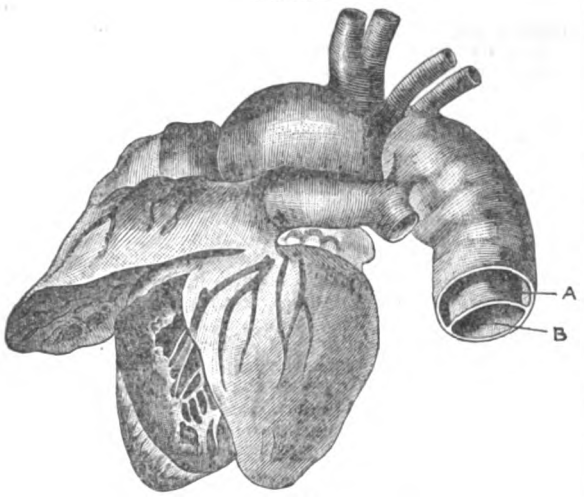
FIG. 1.

Right radial artery.

FIG. 2.

Left radial artery.

bloody streak in the expectoration, nothing unusual occurred during his residence in the infirmary. The diagnosis being aneurysm, the patient was treated by rest in bed, iodide of potassium, and calmatives, and under this he improved. In the month of December, 1890, he left the hospital.



The patient was readmitted on Nov. 17th, 1891, complaining of great difficulty of breathing, cough, slight swelling of feet, of pain in the left arm, and of increasing general weakness. There was nothing special to note regarding patient's condition since he left the infirmary a year ago, except the following:—The right radial pulse could scarcely be felt, the left radial artery was normal in size, and its pulse was water-hammer in character. The right facial artery could not be felt pulsating, whilst the left pulsated normally. The right carotid pulsated very feebly compared to the left. The urine contained a trace of albumen, but this gradually disappeared. There was still to be heard over the aortic area double murmurs, and in the lungs a few rhonchi and small râles, particularly at the base. Within a fortnight he had so far improved that he left the infirmary, but only to return on Dec. 19th, his symptoms having meanwhile increased in severity. The dulness over the manubrium sterni was now more pronounced, and a very distinct thrill was conveyed to the hand placed over it. The urine again showed the presence of albumen, and the expectoration contained small quantities of blood. The cardiac murmurs remained unaltered; there was marked pulsation in the episternal notch. The systolic murmur over the chest posteriorly was heard with greater distinctness to the left of the spine. The pain complained of was referred principally to the left side. The patient gradually got worse. On Jan. 25th, 1892, his pulse was 122; respiration 50; expectoration was occasionally bloody. There was œdema of both forearms, but this was more marked in the left. There was considerable œdema of the lower extremities. Cardiac murmurs remained as before; the diastolic murmur was heard principally to the right of the sternum; no tracheal tugging or whiffing. The whole of the manubrium sterni was very dull on percussion. The patient died on Feb. 2nd. All through the period of observation the patient suffered very little from dyspnœa; there was nothing at all paroxysmal in regard to it. His complaint was one of swelling of the feet and scrotum—long before, however, these became œdematous—and of uneasy flatulent sensations; also of an indescribable sense of feeling ill all over without being able to state where or how. There was never anything like the very severe pain which is present when an aortic aneurysm is pressing upon nerve or bone, but a sensation simply of feeling very ill without the patient being able to localise or describe his symptoms.

Necropsy.—Lower extremities œdematous. Lungs: fluid in left pleural cavity, but not much; right lung, adherent at apex, contained infarcts. Heart enormously hypertrophied, weighed with aorta 2 lb. 6 oz. Aortic arch was dilated. Aortic valves incompetent; left ventricle was hypertrophied and dilated. The innominate artery was dilated and thrombosed; the common iliac arteries were also dilated and thrombosed. On careful examination, the whole of the arch of the aorta was found to be dilated, and as this dilatation affected the ascending and descending portions of the arch, it gave to the transverse part a puckered appearance, the resemblance being not unlike an hour-glass. Slitting up the aorta, it was noticed that the bulging of the ascending portion of the arch was due to a dissecting aneurysm which had taken its origin about half an inch below the commencement of the innominate artery, and had passed down towards, and had almost ruptured into, the right auricle. Its capacity was such that it could contain a bantam's egg. The innominate artery just before it bifurcates was incompletely blocked by a dense, hard, white thrombus. This thrombus extended into and *completely* blocked the right carotid artery, whilst it also extended into the right subclavian artery (the block here was not complete—there was left a small channel by the side of the clot, and along this blood had easily passed). The right carotid artery, whilst it had its channel completely blocked, yet blood had passed into the upper reaches of that vessel by a channel which communicated with, or rather had taken its origin in, the dissecting aneurysm which arose from the ascending part of the arch of the aorta. In this way, and this only—viz., by a dissecting channel—had blood reached the right side of the face, there being a direct opening of this dissecting aneurysm into the normal channel of the carotid artery a little distance above the termination of the thrombus. The transverse part of the arch was puckered and atheromatous. The mouths of the left carotid and subclavian arteries were patent and healthy. At the junction of the transverse and descending portions of the arch of the aorta another dissecting aneurysm was observed. (Fig. 3.) It had an aperture which admitted the tips of four fingers. This aneurysm passed forwards and upwards almost to the origin of the left subclavian artery; here it only lay in front of the upper portion of the descending aorta. From this the aneurysm extended all the way down to within two inches of

Digitized by Google

the bifurcation of the abdominal aorta, but as it descended the aneurysm had become considerably wider; it had extended laterally so as to encircle two-thirds of the aorta. This dissecting aneurysm was formed between the middle and external coats of the vessel, so that when a cross-section of the aorta was made it was found to be composed

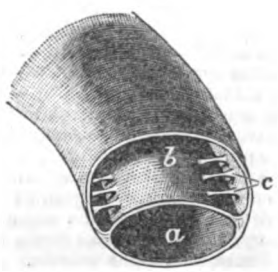


FIG. 3.

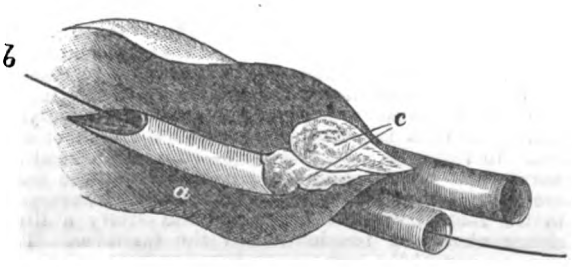
A, Dissecting aneurysm. B, Normal aorta.



of a double tube (Fig. 4), the anterior (i.e., the larger) of which (*b*) was a dissecting aneurysm, and the posterior or smaller tube (*a*) was composed anteriorly of the middle and internal coats of the aorta; whilst the wall lying behind contained all the normal three coats of the vessel. On looking down through a section of *b*, numerous cord-like structures, evidently intercostal arteries, were seen running across the aneurysm from the antero-lateral wall. Possibly

a few of the more delicate cords were simply enlarged and thickened vasa vasorum. Both iliac arteries were firm, and contained clot; they were equal in thickness to the middle finger. The channel of the right iliac artery was patent, but a dissecting aneurysm which commenced at the origin of the external and internal iliac arteries passed upwards in front of the vessel above the bifurcation of the abdominal aorta, but it was not in any way continuous with the dissecting aneurysm which extended from the arch of the aorta. The left iliac artery was extremely atheromatous, and contained several small calcareous plates. Lying in front of this vessel was also a dissecting aneurysm stretching from the upper part of the external iliac artery to the bifurcation of the abdominal aorta. Each dissecting iliac aneurysm was filled with firm white clot. So far as the heart was concerned there was not much to note. The mitral valve was healthy; the mitral orifice was dilated, it admitted the tips of four fingers; the wall of the left ventricle was half an inch thick; that of the right ventricle was extremely thin; the tricuspid orifice was dilated, and admitted the tips of six fingers. The liver was enlarged and nutmeggy; there was gummatous thickening of the capsule. The spleen was small. The kidneys were small, firm, and puckered on the surface.

This case of dissecting aneurysm was one of the most extensive that I find recorded. Fagge[1] reports a case where nearly the whole of the aorta was involved, the symptoms present being intense cardiac pain accompanied by cyanosis and pallor. Professor Finny[2] exhibited a specimen at a meeting of the Academy of Medicine in Ireland, where an aneurysm commencing in the thoracic aorta, about two inches above the diaphragm, dissected its way between the laminæ of the middle coat, along the anterior two-thirds of the vessel, down the whole length of the aorta, to the termination of the common iliac arteries. The aorta and iliacs were thus divided into double tubes. Although Professor Finny's patient was the subject of a dissecting aneurysm of very great dimensions, in his case, just as in mine, there were no special symptoms present such as would have enabled one to have diagnosed the peculiar nature of the aneurysm.

Newcastle-on-Tyne.

PASTEUR'S ANTI-RABIC INOCULATIONS.

BY T. WHITESIDE HIME, B.A., M.D., &c.

THE certainty and permanence of Pasteur's anti-rabic treatment, as proved by the only reliable test, experiment, are so remarkably illustrated by the following cases that I feel sure they will be interesting to readers of THE LANCET. And perhaps all the more so as I have personal knowledge relating to them, and do not report them merely as good news from those distant countries where the hills are always green. They are further illustrative of the never failing courtesy and kindness shown by Pasteur himself, Roux, and the other chiefs of the Institute, to all who are interested in the work carried on there. It will afford general pleasure when I add that quite recently I found Pasteur,

"Il maestro di color che sanno,"

in excellent health, and supervising the inoculation of the patients at the institute, of whom there were ninety-five, collected from all parts—Arabs of the desert, Belgians, Portuguese, French, and other nationalities.

CASE 1.—While in Paris in October, 1889, I mentioned to Pasteur that I was anxious to make some inoculations with rabic virus, so as to test the efficacy of his preventive method, at the institute. He at once said I could do so, and, further, he was so kind as to direct that I should be provided with everything necessary for the purpose. That I should be anxious to do the experiments there will not surprise those who know the difficulties which surround research of this kind in England. We are practically obliged to accept unchallenged every alleged discovery from abroad as to methods of preventing and curing disease, &c., or else we must go abroad in order to test their truth without being molested. Operative and other methods of treating disease may indeed be tried here experimentally on men; but if anyone influenced by love of his kind prefers to test them first on lower animals, he will find that his path, if not absolutely closed, is a very thorny one indeed. The subject of this experiment was a bitch, which I named "Betty." The rabic virus used for the inoculation was the greatly intensified kind known as "laboratory virus." This virus

[1] Medical Times and Gazette, 1869.
[2] THE LANCET, vol. ii. 1885, p. 99.

Digitized by Google

originates with ordinary virus of the mad dog, which is now technically termed "street rabies." This street virus, when inoculated under the dura mater, is found to have a period of incubation which varies usually from sixteen or seventeen to twenty days, and kills within three or four days after the first symptoms have appeared. After passage through a considerable number of rabbits the street virus acquires gradually a shorter and less variable period of incubation, and ultimately it attains a degree of fixedness in this respect such as is hardly known in any other virus. The appearances of the initial symptom may with almost unerring certainty be expected between the fifth and the sixth day after inoculation, and death between the tenth and eleventh. The virus which I employed for the inoculation of "Betty" was this intensely strong virus, and was obtained from a guinea-pig which had died of rabies only a few minutes previously, on Oct. 4th, 1889. Having first chloroformed her, I trepanned and injected beneath the dura mater a few drops of the emulsified medulla of the guinea-pig. Immediately afterwards a rabbit was chloroformed and inoculated in the same way and with the same material, to serve as a witness. Inoculations of rabic virus under the dura mater invariably take, as do intra-ocular injections. "Betty" recovered immediately from the effects of the chloroform and operation, as is invariably the case when it has been properly done. On the day after the inoculation a course of preventive treatment was commenced for "Betty," but not for the rabbit, in order to see what difference there would be in the results. The former was treated according to the same method as the human patients, and like them received a series of injections of emulsified medullæ, the first of which was from a rabbit which had died of rabies fourteen days previously, while the last was only three days old. Each day, after the human patients had been injected at the institute, I obtained some of the liquid remaining over, of the required strength, and injected "Betty" subcutaneously with it. The result of the treatment was a perfect success; for whereas the rabbit which received no preventive treatment was attacked and died of rabies in the usual course, "Betty" had no kind of bad result from the inoculation. She lived a peaceful and evidently happy life, without any indication of disease, until at the end of over two years and a half she had to be sent to the happy hunting grounds in order to make room in the kennels.

CASE 2.—This is even a more remarkable experiment than the preceding. Unlike "Betty," the animals experimented on were first subjected to a course of preventive treatment, and were subsequently inoculated with rabic virus.—March 22nd, 1889: Three dogs, which may be called *A*, *B*, and *C*, received their first preventive injection of attenuated rabic emulsion containing medulla fourteen days old. The course of treatment was continued in the usual way until medulla of the third day had been injected. The subsequent history of these three dogs was as follows:—

June 1st, 1889.—The dog *A*, along with a witness dog and rabbit, were inoculated under the dura mater with fresh rabic virus of the street. The witnesses were both seized with the initial symptoms of rabies on the seventh day afterwards, and both died of rabies on the eleventh day, whilst *A* continued in perfect health. *B* and *C* were inoculated in the eye on the same day and with the same virus. This mode of inoculation, it may be mentioned, is as effective and certain as the subdural inoculation, and when done antiseptically (as every operation should be) causes no local disturbance whatever. No symptoms of rabies or any other untoward result followed this injection in the case of *B* and *C*.

Aug. 16th.—On this day *B* and *C* received for the second time an intra-ocular injection of rabic virus of the street, and a dog witness was inoculated at the same time. The witness exhibited the first symptoms of rabies on Sept. 2nd (the seventeenth day), and died on Sept. 5th (twentieth day) of paralytic rabies, while the dogs *B* and *C* continued in perfect health.

Nov. 27th.—The dogs *B* and *C* were inoculated in the eye for the third time with ordinary street virus (rabic), along with a dog and rabbit as witnesses. The dog and rabbit witnesses were attacked with the first symptoms of rabies on Jan. 2nd, 1890, and both died of rabies, while *B* and *C* suffered no harm whatever.

Dec. 17th, 1891.—The dog *A* was for the second time inoculated in the eye with canine rabic virus of the street, along with a rabbit witness. The latter was attacked with symptoms of rabies on Jan. 2nd, 1892 (sixteenth day), and died, as usual, of rabies, while the dog never showed any abnormal symptoms.

On the day of my last visit to the Pasteur Institute, April 15th, 1892, all three dogs, *A*, *B*, and *C*, were alive and in perfect health.

No commentary is needed on these remarkable cases, illustrating, in a way which leaves no room for doubt, the success of the Pasteur method in protecting against rabies, whether applied before inoculation of rabic virus or after. It is desirable, however, to draw attention to the fact that the animals experimented on were inoculated in a manner which never fails to take (under the dura mater or in the eye). It cannot, therefore, be assumed that they may have escaped infection in the same way as persons and animals sometimes do when bitten in the ordinary manner by rabid animals. These animals were subjected to a test which involves the certainty of infection and death from rabies, and yet the Pasteur method has proved sufficient to protect them. No animal or person is ever subjected to such a test in the ordinary course of life. But there is another point which forcibly illustrates the efficacy of the Pasteur method. The virus which I used for inoculating "Betty" was not the ordinary street virus derived directly from the rabid dog; it was much stronger—the laboratory virus (rabic), one which kills in far less time than is usually observed where infection has followed a bite by a rabid dog. If the Pasteur method can protect against the action of the intensified "laboratory virus" actually deposited on the surface of the pia mater after trepanning, is there not the strongest corroboration afforded to the other existing evidence that it can protect against the action of the ordinary, and much less active, virus of street rabies inoculated by a bite in the usual way?

The permanence of the protection is also shown in the most satisfactory manner. The dog *A* was preventively treated in March, 1889, and was found protected when inoculated for the third time on Dec. 17th, 1891. But there are many other witnesses of the durability of the protection who attest that it lasts very much longer. There are many of the dogs which were used by Pasteur for his earliest experiments nine and ten years ago still living which have been proved at recent dates to be still protected. I assisted myself in 1889 at the fourth inoculation of one of these dogs. The animal was trepanned for the second time, and inoculated under the dura mater without the least ill effect. This dog had also received a subcutaneous inoculation of rabic virus, as well as an intravenous injection, but proved refractory to all the four attempts to infect it. The *rationale* of the method is still involved in some obscurity, and up to the present all attempts to isolate the virus have failed. Neither microscopic examination nor the method of artificial culture has revealed anything distinctive. All the experiments which I have tried of cultivating in bouillon, in blood, and even in aseptic brain substance have failed, the virus invariably becoming inert, and, so far as I know, the results obtained by others have not been more successful. But I think it is not improbable that the *modus operandi* of the method may be strictly analogous to what is known to be the case with vaccinia and variola.[1] Vaccine takes about eight days to infect the system and protect it, while the variolous virus, being slower in its action, takes fourteen days, "the precise time being after thirteen times twenty-four hours have elapsed from the moment of taking the disease" (Marson). Suppose, then, a person to have absorbed the virus of small-pox on a Monday; if he be vaccinated on the ensuing Monday, Tuesday, or Wednesday, the vaccination will have time to take full effect and protect the system before the small-pox virus; if the vaccination is not done until Thursday, it will be partially effective, because the vaccinia will have already reached the commencement of the protective stage, while the variolous infection is still in its incubative stage, and the patient will have "modified small-pox"; if the vaccination, however, be delayed until the Friday, it will be useless—the variolous poison will have had time to infect the whole system before the vaccine virus.

[1] The employment of the term "vaccine" as signifying *any protective virus* in the recent sense—e.g., the "vaccine" of anthrax—is very unfortunate, and undoubtedly is calculated to lead to confusion. Jenner introduced the word vaccine to designate the virus of vaccinia, because the disease is derived from the cow (Lat. *vacca*, cow). It is indefensible to apply the same term to a different virus &c., derived from a different animal, especially when its employment in the special sense has been consecrated by long use, and has come to be universally understood to mean one thing only.

Digitized by Google

In the case of the anti-rabic preventive method analogy would seem to sanction a similar explanation. The virus of canine rabies, after several passages through the rabbit, acquires a period of incubation of from five to six days, while that of the ordinary rabid dog "of the street" is more than twice as long when inoculated under the dura mater, and is usually at least eight to nine times as long in taking effect after an ordinary bite. Hence there is time for the short-period rabbit virus to take effect before the long-period canine virus. The early protective inoculations are made with rabbit virus which has been modified (attenuated or diminished in quantity?) by keeping,[2] and is incapable of producing rabies, but the later doses are capable of causing rabies when inoculated on an animal not protected by previous weak doses. This last fact is in itself an indubitable proof of the efficacy of the treatment, and is observed among the human patients as well as animals. The whole procedure is therefore dependent on Pasteur's discoveries of how to abbreviate the period of incubation of the virus by passage through the rabbit, and how to inoculate so as to produce the disease with positive certainty by intra-cranial or intra-ocular inoculation.

Those who are aware of the preceding facts cannot but be lost in amazement at the combined ignorance and audacity of those who assert by word and print that the protective virus is regularly obtained from dogs. The assertion is made to create prejudice against a scientific method of saving human and animal life. The allegation that the noble dogs, man's faithful companions and friends, are sacrificed in a wholesale way to save the life of that brute man, is a safe way to excite the passion of certain people, even though the allegation is devoid of truth!

There are persons who are not afraid to assert that the deaths of the control animals are due to the operation, either through shock or by septic infection. The answer is simple: 1. It is impossible to extract from an animal which has died of "shock" a specific virus which has an invariable period of incubation, kills with certainty within a definite period, and can be inoculated on other animals in series *ad infinitum*, so as infallibly to reproduce the same disease ("shock," it may at the same time be observed, is not in any sense a "disease" of a specific type). 2. The symptoms of rabies and those of shock are absolutely different. 3. The brain of the animal is not injured during the inoculation. If it be intentionally injured, without the introduction of rabic virus, the animal will show none of the symptoms of rabies, even if it should die (which depends on the extent of the injury). 4. The death is not due to septic infection, for (*a*) the symptoms are utterly different, and (*b*) the medulla of a rabbit which has died of septicæmia caused by the subdural injection of septic matter will not give septicæmia when inoculated in the same way into another rabbit. That the operation is *per se* harmless is evident to those who have seen rabbits which have received injections of inert substances (distilled water, bouillon, healthy medulla, &c.) under the dura mater. Within a few minutes after the operation, and immediately after the effects of the chloroform have passed off, these animals will run about, eat, and indulge in their gambols, unconscious of what has happened. Their after-lives, free from pain or ache, or any variation from the behaviour of other rabbits, prove that the operation does not affect them in any way injuriously. Of course a bungler may do damage in performing this operation, just as a barber, instead of shaving his victim, may by a mistake cut his throat! Up to the end of 1891 there had been treated at the Paris Institute a total of 10,992 persons, of whom 62 died, or 0·56 per cent. The rate of mortality has steadily declined from 0·94 in 1886, to the remarkably low figure of 0·19 in 1891. Of the 1563 cases treated in 1891, no fewer than 42 were from this country. The remarkable success of Professor Murri, of Bologna, in curing a patient, already attacked by hydrophobia, is perhaps the most startling outcome of Pasteur's method, being a fresh victory for science over a disease which has hitherto proved invincible. I hope to give full details of this most interesting case in a future number of THE LANCET.

Bradford, Yorks.

[2] The rabic virus can also be attenuated by passage through the monkey. A dog inoculated with rabic virus after passage through five monkeys showed an incubation period of no less than fifty-eight days, although it had been inoculated in the arachnoid space. In his earlier experiments Pasteur employed the virus thus attenuated for protective inoculations, but owing to the difficulty of dealing with such delicate and scarce animals, he abandoned it. The modifications of the rabic virus by passage through different animals, intensification by passage through rabbits, attenuation by passage through monkeys, are strictly analogous to the behaviour of the virus of swine plague (*rouget*), as described first by Pasteur, Dec. 26th, 1885 (Bull. de l'Académie des Sciences). The virus of this disease becomes much intensified by passage through the pigeon, the period of incubation is shortened, and death ensues sooner. The virus is also rendered more fatal to pigs. But if the virus taken from the pig be passed through a series of rabbits it will be found that, though it continues fatal to them, it becomes so attenuated that it may be inoculated on pigs without the least danger. Indeed, this attenuated virus is employed by Pasteur as a protective against the most virulent form of the infective agent. Pigs may be inoculated with the latter after protection with the former, and will be found to have acquired complete immunity. This condition does not last as long as the immunity conferred by Pasteurian inoculations against rabies, as shown above, only holding good for about one year. But it is rare, indeed, for a pig to reach a much more advanced age than twelve or fifteen months, that being the flower of his age, during which he is killed. It can hardly be doubted that vaccine is the virus of variola, modified in an analogous way by passage through bovines, and that herein lies its power in protecting against small-pox.

THE HOLY PLACES OF ARABIA: THEIR WATER-SUPPLY AND GENERAL SANITARY CONDITION.

BY JOHN WORTABET, M.D.

THE Koran enjoins pilgrimage on all believers who are able to perform it, as an absolute duty which cannot be neglected without great offence to God. This condition of "ability" is explained by the most eminent school of Mohammedan theology as including health, safety of the way by land and sea, and the possession of a sufficient amount of money to discharge the intending pilgrim's debts, to provide for his family during his absence, and to enable him to make the journey with comfort on a camel or other beast of burden. The two chief places which are annually visited by Mohammedan pilgrims are Mecca and Medina—the first containing the sacred mosque called "The House of God," and the second having the tomb of the Prophet. They both lie inland, and are accessible to pilgrims either from Damascus through the desert, or by the Red Sea and Tidda, which is the port of Mecca, while Yambu holds the same relation to Medina, though very few pilgrims go into Arabia or come away from it through the latter port. The route most generally followed is the sea voyage to Tidda, a journey to Mecca and Medina, and a return to Mecca and Tidda, the whole pilgrimage taking usually about four months. The Mohammedan month Za'l Hijja ("the month of pilgrimage") is that on which the pilgrims are gathered at Mecca and Medina, and as the Mohammedan year is lunar, with no intercalary month every three years to make up the difference between it and the solar year, the month of pilgrimage recedes by ten days every year, and is thus ever changing its relation to the seasons. The annual number of pilgrims must vary from year to year, but it is computed by the most reliable observers as being from 50,000 to 80,000. No Christian is allowed to visit these holy places, and our sources of information are the accounts given by Arabian writers, Mohammedan visitors, and the Christian travellers Ali Bey (1807), Burckhardt (1814), and Burton (1853), who made the pilgrimage under assumed Mohammedan names. To these must be added the valuable report of Assistant Surgeon Abdur Razzak, who was sent by the Indian Government to accompany the pilgrims in 1878–1879. From these several authorities, and from the annual reports to the Indian Government by its agents, the following abstract is made:—

Tidda is a town of about 20,000 inhabitants, and is built, to the extent of a mile in length, on a slight eminence of land which rises from the sea-shore. It contains a number of large lodging-houses for pilgrims, built in flats, each room taking from ten to twenty people, and they are often highly crowded, while the uncleanly habits of the occupants and the insanitary condition of the latrines combine to produce a fruitful source of disease—such as fever, dysentery, and diarrhœa. The sewerage system is the same as in other Oriental towns; the excreta are conducted by depending passages into sinks, which may or may not communicate with each other, and where, partly by absorption into the soil and partly by exhalation into the atmosphere, the sewage is disposed of. The streets are supposed

to be swept every day; but this is said to be carried out only in the market place, while the by-streets and alleys are unattended to, and are often beds of accumulated refuse and dirt. From 30,000 to 50,000 pilgrims pass through the town every year to Mecca, and again on their return. Fortunately their stay is short, and they come and go in parties. The water-supply of Tidda is provided by large tanks of rain water, which, however, are often insufficient, and it is said that a benevolent Mohammedan from India has lately brought a large and wholesome supply from the springs of Hadda, a midway station between Tidda and Mecca. Mecca is about forty-five miles due east from Tidda, and the journey is generally made on two successive nights—most of the day between them being spent at Hadda. The road is sandy and barren, and soon leads to the hill country, where Mecca is situated at the height of 2000 ft. above the level of the sea. Soon after leaving Hadda two high pillars indicate the boundary of the Holy Land, where the pilgrim puts on his garb of two seamless cloths, one around his loins and the other to cover the upper part of his body, leaving the head bare, and begins his cry of "Allahumma labbarik," which he continues from time to time throughout his stay within the sacred precincts, and which means, "Here I am, O God, in obedience to Thy call!"

Mecca lies in a narrow and sandy valley, which is described in the Koran as being "sterile," and which extends from north to south. The hills which form the two sides of the valley rise to the height of from 200 ft. to 500 ft., black, waterless, and utterly barren, and are, according to Ali Bey, of granite formation. The town occupies the broadest part of the valley, though many of the houses are on the sides of the hills, and is about three miles long. The population is estimated at more than 50,000, and is doubled or trebled during the season of pilgrimage. The main street which runs through the town is broad, and kept clean by daily sweeping, while the other streets are from ten to twelve yards wide, and are described by the latest visitor—Dr. Abdur Razzak, 1879—as being wholly neglected and extremely dirty. The houses are built of stone, and vary from two to five storeys in height, with numerous windows towards the streets; but the rooms are generally small, the ceiling low, and ventilation and the admission of light imperfectly provided for. Most of these houses are let during the annual season to pilgrims who are able to pay for them. A good number of large lodging-houses, built by rich and benevolent Indians, receive freely the poor class of their countrymen. The air is said to be dry, and would be bracing if it were not for the great heat. Abdur Razzak speaks of a high temperature in December, Benton says that clothing was intolerable during the day in September, and Ali Bey, who seems to have been the only one who took any thermometrical records, puts the maximum heat in February at 87°, and the minimum at 67·5° F. The latter saw but one flower during all his stay at Mecca (from January 23rd to March 2nd), and that was on his way to Arafat. He says: "The aridity of the country is such that there is hardly a plant to be seen near the city or upon the neighbouring mountains." All the vegetables and fruits consumed in Mecca are brought from Taif, a well-watered and fertile plain, two days' journey due east.

The sewerage of the houses and the system of drainage are described by Dr. Abdur Razzak as follows. After speaking of the situation of the watercloosets as being always at or near the entrance of the house or a section of it, if it is large, he says: "There is no proper outlet for the water of these privies, or for the excretions (nightsoil), nor is there any system of drainage in the city. Not a sewer or a surface drain exists. Rain being scarce and the soil very dry, there is not much necessity for drains in the opinion of the inhabitants. The only drainage arrangement in all the houses is that a central deep drain is cut out in a convenient part of the house, and with it all the privies in the house are connected by covered drains, in which the slope is very great, so that anything falling or lying on the highest end is very quickly washed down into the central drain. Besides these, a very large and oblong pit is dug out in the middle of the street, opposite the house, which answers the purpose of a cesspool, and with it the central drain of the house is connected." As a natural consequence, he says, the exhalations are highly offensive and noxious.

The original water-supply of Mecca consisted of a few cisterns of rain water and some brackish spring wells, of which the famous well of Zemzem is one. These latter are said by Ali Bey to be of the same depth and temperature, and he believes that they are all supplied by a sheet of water fifty-five feet under the surface, and formed by the percolation of rain water through saline materials, which give it a brackish taste. None of these wells, however, are now used except that of Zemzem, which is reputed to be the spring pointed out to Hagar by an angel, and whose waters are drunk by all pilgrims on religious grounds. The present water-supply is amply furnished by the aqueduct known as that of Zobaida. This lady was the wife of Harun-ar-Raschid (A.H. 170), and having made a pilgrimage with her husband to Mecca, and observed how highly meritorious it would be to provide the holy city with abundant and wholesome water, undertook the great task of having it brought from a considerable distance. Arab historians have given us a detailed account of this stupendous work, which cost more than two millions of pounds of our present currency. The water was conducted in an aqueduct of solid masonry from two copious springs, which take their origin from a chain of mountains to the east of Arafat, and to which six other fountains were added in the plains which lie between this hill and the eastern mountains. The aqueduct, after surrounding Arafat, where all the pilgrims gather on the 9th of Zu'l Hijja, follows their way by Muzdalafe and Muna to Mecca. During the eleven centuries which have passed since its first construction it has often been out of repair, and the water ceased to flow, to the great distress of the pilgrims. Restored in A.H. 634, 726, 811, 821, and 875 by Mohammedan kings or princes, the water became again so scarce in 930 that the historian El Hanafy, who was there in that year, witnessed the great sufferings of the pilgrims, and bought at Arafat a small water skin for a piece of gold. The work of reparation was taken up this time again by a lady—the wife of Solyman the Magnificent,—who, in A.H. 969, appointed able and energetic men to execute her orders. They cleared the original springs of Hunain and Noman to the east of Arafat, repaired the aqueduct as far as Zobaida's Well beyond Muna, and channelled the rock to the distance of 2000 yards into Mecca. This work was executed in ten years, and was as thoroughly done as that of Zobaida; and since that date, with occasional repairs, the water has been abundant.

Abdur Razzak says that the water is very sweet and light, and is supplied by means of five or six reservoirs distributed in different parts of the city. The largest of these is near the market place, where the water is let out through a number of perforated holes into a shallow trough, and where the professional water-carriers fill their water skins directly from the taps. "There is a stopcock at the mouth of the aqueduct, and there are stated hours at which the cock is turned open and the water carriers are allowed to fill; no water can be had after nightfall." Burckhardt (A.D. 1814) says that remains of the aqueduct were seen in the lowest part of the city, "and its water, after supplying the town, was conducted this way into the southern valley, where it served to irrigate some fields." The mosque of El Kaaba, or *Beit-allah*, occupies a central portion of the town. It is believed to be built after the pattern of a similar structure in heaven, which is ever circumambulated by advising angels. In like manner, the pilgrim does the same duty in his prescribed garb, and offers his prayers at the holy spot. While this is the most essential part of pilgrimage, other duties incumbent on the pilgrim are to attend the prayers and sermon at Arafat on the ninth day of "the month of pilgrimage," to return to Mecca on the following day for the great Feast of Sacrifices, and to visit the Prophet's tomb at Medina.

Arafat is a hill (the "Hill of Mercy"), where it is believed Adam first met Eve after their expulsion from Paradise. It rises to the height of about 200 feet from a plain some ten miles long and five wide. All the pilgrims encamp on that day in the plain below, while the Kadi of Mecca preaches the annual sermon of three hours' duration on the hill, the people spending the time in prayer, and calling out the formula *Labbarik!* ("Here I am, O God!") The aqueduct of Zobaida runs round the hill, and supplies the pilgrims with abundant water. The water is let out into basins, of which Ali Bey (A.D. 1807) counted fourteen, "which furnish a great abundance of excellent water, and which serve also for the pilgrims

Digitized by Google

to wash themselves." In the times of Abdur Razzak, "there were three of these large tanks, from which people were allowed to take away as much water as they liked, but nobody was allowed to wash anything in it. A Turkish soldier, with fixed bayonet, but in a pilgrim's garb, was standing guard over each. During the day, however, when the ceremonies of the Haj were going on, the attention of these guards being diverted from their duty, the water had become dirty from the people not taking care when they filled their water skins at the edge of the tank." Arafat lies about twenty miles (Burton says only twelve miles) due east of Mecca, and, according to Ali Bey and Burton, is chiefly of granite formation. It is on the plain, where all the pilgrims are encamped for one day, that an approximate guess can be made of their number. Ali Bey (1807) estimates it at 83,000; Burckhardt (1814), 70,000; Burton (1853), 50,000; and Abdur Razzak (1879), 60,000. The Mohammedans believe, on the strength of a well-sustained traditional saying of the Prophet, that if the number is ever less than 600,000 the deficiency is made up by angels in human form. Leaving Arafat at dusk of the same day the pilgrims start for Muzdalafe, where they spend the night, and reach Muna on the following morning. Muna is the place where animals are slaughtered as an offering to God, in commemoration of the sacrifice made by Abraham of a sheep instead of Ishmael, his son, whom he had been commanded to offer. This is the great feast of the Mohammedans, and is called the "Feast of Sacrifices." Muna is described as a long and narrow town, situated in a hollow, where the heat is very great even in December. Here, on the 10th of Zu'l Hajja, all the pilgrims meet again, and the sanitary arrangements are said to be most unsatisfactory. The main street alone is kept clean, the waterclosets are few and badly constructed, and the crowding in both the houses and in the open is very great. The slaughter-houses, where several thousand animals, chiefly sheep, are killed, are few, and the trenches dug for receiving the carcases are insufficient for the purpose. Before the pilgrims leave the place the odour, owing to speedy decomposition, becomes not only highly offensive, but very noxious. The number of sheep killed is uncertain, for while Burton estimates it at 6000, Abdur Razzak raises it to something like 100,000. The latter says that many fall ill with vomiting, diarrhœa, dysentery, and fever, either then and there or soon after their return to Mecca. In Burckhardt's time (1814) it was even worse. He says: "Poor Hadjys, worn out with disease and hunger, are seen dragging their emaciated bodies along the columns of El Kaaba, and when no longer able to stretch forth their hand to ask the passengers for charity, they place a bowl to receive alms near the mat on which they lay themselves. When their last moments approach they cover themselves with their tattered garments, and often a whole day passes before it is discovered that they are dead."

The water-supply seems to be now abundant, and is sold to the pilgrims in small water skins. The distance from Muna to Mecca is about four miles, and the pilgrims return on the third day of the feast to the holy city to perform what is called "the lesser pilgrimage," which means a short journey of a few miles from Mecca, a return to it in the pilgrim's garb, and circumambulating El Kaaba. If the pilgrim has not visited El Medina before coming to Mecca he now does this duty. The distance between these two places is twelve days' journey — slightly up-hill — and the stopping stages are always made where there are wells of water, from which the travellers can be supplied for the night, and where they fill their water skins for the following day. The quality of the water is mostly saline, and drinkable only from necessity. El Medina ("The City," or the City of the Prophet) is a town of about 20,000 inhabitants, lying in a vast plain, bounded by two chains of hills to the east and west, and is supposed by Mr. Doughty to be about 3000 feet above the level of the sea. After the great heat of Mecca, Abdur Razzak found it very cold, the thermometer falling to 56°. Its streets are kept clean and daily inspected by zaptiehs. "The water-supply," he says, "is the best in the Hedjaz, and perhaps it would be creditable to any civilised country of the present day. Underground aqueducts run through the whole city, and in every quarter there is a reservoir below the level of the ground, with stone steps leading to it, where stopcocks, arranged in a row, regulate the expenditure of water, and where water carriers fill their water skins. A stream of the purest water, which commences at Kubba, a place about two miles from the city, flows through it, and after passing through the aqueducts is carried out of the city to water the date plantations, which are plentiful around Medina." The public latrines, he adds, are more plentiful and far superior to those in Mecca, "and as the government of the place takes care not to have more than a certain number of pilgrims during a given time, there is never any crowding." "If the air of Medina had not been so bracing, every pilgrim would have fallen sick after the privations suffered on the journey from Mecca." The chief object of visiting El Medina is to see, and to pray near, the tomb of the Prophet and his immediate friends. The stay there does not generally exceed a week. The pilgrims then separate, some to return by land caravan to Damascus, which occupies about thirty stages, some to Yambu, the seaport of El Medina and about four days' journey from it, and the largest number to Mecca and Tidda.

In comparing the accounts given by trustworthy travellers who visited these places during the present century (1807–1879), we find a marked improvement in their sanitary condition. This is doubtless due to the better government of these days, especially under the rule of his Majesty the present Sultan, who is well known to take a special interest in those hygienic measures the value of which science and experience have put beyond all doubt. From the later reports of the Sanitary Commission of India (1884–1890) we have a gratifying confirmation of this fact, for they all tell of annual efforts, more or less strenuous, made by the local authorities to improve the water-supply, the surface cleanliness, and the prompt and more effectual burial of slaughtered animals at Muna. The tanks of water are cleaned and drained, and guards see that no water at Mecca is used except that taken directly from stopcocks. A generous Indian prince (the Nawab of Rampur) has "constructed a large reservoir in Muna, fed by a branch of the Zobaida aqueduct. The water from this reservoir was drawn (1886) from stopcocks, and measures taken to prevent the pollution of the stored water. The reservoir, however, is not large enough to supply water to all present, and it is reported that at least two others would be necessary for all requirements." Muna, which has always been noted for its filthiness, was remarkably clean in 1886; but there is still much room for improvement. Engineering skill in conveying pure water and keeping it free from the possibility of pollution, stringent measures for insuring perfect cleanliness of all the streets and alleys, improved sewerage, the prevention of overcrowding, a thorough disposal of the sacrificed animals at Muna, greater efficiency of the hospitals of Mecca, Medina, and Tidda, rigid inspection of pilgrim ships coming from infected places, and, in case of an epidemic, the dispersion of pilgrims as soon as they have performed the duties prescribed by their religion, which was wisely ordered by the authorities this year (1891) on the outbreak of cholera among them with very considerable success, are means which the Turkish Government alone can carry out, and which will do much to diminish the violence of epidemics, disease, and mortality. It has always been the glory and ambition of Mohammedan kings to do their utmost for the safety, well-being, and comfort of pilgrims, and it may now be the most glorious act of the reign of his Majesty the present Sultan to see that the most approved principles of modern sanitary science are efficiently carried out in the holy places of Arabia. But on the Indian Government also lies a large share of responsibility. For not only is there the fact that cholera, which has visited Arabia in 1883, 1890, and 1891, during the last few years, is always imported from India; but, according to the *Times of India* (quoted in *The Times* weekly edition, July 10th, 1891), more than a third of the pilgrims leaving Bombay for Mecca never return. "Thus, of 64,638 pilgrims who left in the six years ending 1890, 22 449 were missing." Surely for this appalling list of mortality and unrecorded suffering the Indian Government should devise some preventive means which may be within its legitimate power. The measures indicated by Abdur Razzak may be adopted, in which modification, and if properly carried out, so that no pauper and no diseased person, or one coming from some part of the country where cholera is known to exist, may be allowed to leave India, this great evil to the Indian pilgrims may be very materially diminished, and the chances of the migration of cholera

with them into Arabia and other adjacent countries considerably lessened if not wholly extinguished.

ANALYSIS MADE IN THE LANCET LABORATORY OF WATER TAKEN FROM HAGAR'S WELL AT MECCA.

In connexion with the above article, we have been favoured by Dr. Wortabet with a sample of the water from the Well of Zemzem, or Hagar's Well, obtained on Jan. 13th last from a returned pilgrim. It will perhaps be within the recollection of some of our readers that a similar sample was forwarded to us in November, 1883, by Dr. W. G. Balfour, and the results of the analysis made for THE LANCET by Professor Heaton were published in our issue of Jan. 5th, 1884, page 33. Nearly nine years, therefore, have elapsed since that sample was taken, and it is interesting and instructive to compare the results of analysis obtained with this sample with those of the sample secured in January last, inasmuch as any difference indicating whether the condition of the water has altered for better or for worse over that comparatively long period will at once be apparent. As a glance, however, at the analysis below will show, what was said of this holy liquid nine years ago may be said of it again at the present time. There are indications that the water is still grossly polluted, although apparently not to the extent reported hitherto. The results of analysis of the two samples bear a distinct resemblance to one another—at any rate as regards kind if not in quantity of impurity. Thus the entire absence of the so-called albuminoid ammonia is again a striking feature in the analysis, and is probably attributable to the completion of the putrefactive process. The nitrates and nitrites are in excessive quantity, and the presence of the latter, which result from the reduction of the former, indicates pretty nearly for certain the pre-existence of readily oxidisable matter, such as sewage. The nitrites occur in so large a quantity that a few drops of the water expel the iodine in an acidified solution of potassium iodide, and also turn to a deep yellow colour, a solution of di-amido-benzene—Griess' well-known reagent for the detection of nitrites. Unfortunately, as the quantity of water at our disposal was only 300 cubic centimetres—a separate estimation of nitrites could not be carried out. The addition of sulphate of iron and strong sulphuric acid to the unconcentrated water resulted in the formation of an intense brown colour, due to disengagement of nitric oxide gas from the nitrates and nitrites. The excessive proportion of free ammonia further testifies to the changes that have taken place consequent on the oxidation of organic matter. Chlorine present in chlorides is extremely high—indeed, the water had a slightly brackish taste, and the total solid matter though considerably less than before afforded distinct evidence of the existence of phosphate. The two analyses are given below, and for the sake of comparison an analysis of the water supplied to London by the Thames companies is appended.

	Grains per Gallon.		
	Mecca.		London.
	1883.	1892.	
Total solids	464·4	235 2	18·00
Chlorine	75·5	40·7	1·5
Nitrogen as nitrate	13·75	4 55	·18
Nitrogen as nitrite	·09		None.
Ammonia	·358	·140	·001
Albuminoid ammonia	None.	None.	·004

Stanley Lane Poole wrote in reference to the analysis in 1883 as follows:—"The analysis of this miraculous water will cause a severe shock to all true believers who read THE LANCET, though from what one knows of the sanitary methods of the East there is nothing surprising in the discovery that the Well of Zemzem is as foul as a good many other saintly springs. Zemzem is in the midst of a thickly built city, where drainage is of a peculiarly primitive description, and the well is almost necessarily affected by the drainings from the countless carcases of beasts which are annually sacrificed by the pilgrims in the neighbouring valley of Muna. It is, however, some satisfaction to remember that muddiness as a source of inspiration has never been held a bar to miraculous effects. Zemzem will doubtless work wonders in spite of the 'completion of the putrefactive process.'"

Our recent analysis indicates that the putrefactive process is still going on, and it follows that the ingress of putrefiable substance has again been permitted.

OUR MISTAKES.

BY WILLIAM MURRAY, M.D., F.R.C.P. LOND.

(Concluded from page 1022.)

IT is interesting to observe how often our cases run in pairs or groups. With the last case fresh in my mind I was called to see a gentleman in the north. On going into his room his wife said, "Do not bother him by many questions." On asking him to tell me of his complaint briefly, he, pointing to the inside of his thigh, said, "I can tell you in three words, 'It is pain there.'" I asked for vaseline, examined the rectum, and found a malignant mass in the pelvis—a sad solution of a case which had misled two excellent practitioners to suppose he suffered from disease of the pelvis of the kidney. These cases show how narrowly we sometimes miss a diagnosis, and show how important it is to take note of these slight and faint hints if we are to save ourselves from failure. We must, however, take heed lest a great success in diagnosis and treatment unduly impresses itself on our minds and we begin to seek for the same thing, and do the same thing in every case. It is easy to yield to this temptation, and we need to guard ourselves. I have again and again seen even great men plant their favourite diagnosis on the most unlikely cases. Two or three patients of a really great physician came to me a few years ago, each stating they had irritation of the ureter, until at last I was able to say, "Oh! I see you have consulted Dr. So-and-so." In each of these cases the true ailment proved to be lateral flexion of the uterus. Not that I have escaped this mental infection, as I am free to admit I may probably have treated irritated ureter for lateral flexion. Nothing short of a large view and a well-balanced mind can save us from this kind of thing.

An illustration of another kind of mistake which sometimes occurs as the result of a paucity of experience and a good deal of science may be here introduced. It also illustrates the danger of the so-called *nimia diligentiæ* in treating a case by everything but the right thing. I was called to see a favourite child of wealthy people in Yorkshire said to be suffering from inflammation of the brain. I found a strong plethoric child, with flushed face and suffused and congested eyes. He was suffering from pain in the head, restlessness and great irritability, together with anorexia and a coated tongue. He was in a darkened room, two nurses were in attendance, and an apparatus for circulating iced water over the head was in active operation. The temperature was taken at frequent intervals, and repeated doses of aconite were being administered. The expression of the child's countenance and his evidently clear intellect did not convey the idea of meningitis to my mind, and I asked when his bowels had acted. No one quite knew, and it was clear they had not acted for a day or two. I gave my opinion to the medical attendant that it was a case of disordered secretions, and insisted on giving three grains of calomel, followed by a dose of senna. We met again in a few hours, and found the patient sitting up in bed quite cheerful and comfortable, after a free purgation, and he was soon quite well. I do not mean to cast any reflection on what is called scientific medicine, but I think an old-fashioned doctor would probably have purged at the outset and saved all this bother. Let us never forget the marvels achieved by our old friend calomel.

To omit the abdomen as the most fruitful field of all sorts of mistakes would be to omit the character of Hamlet from the play. The many different organs contained in it ministering to functions so different as digestion, excretion, assimilation, and reproduction give rise to such enormous varieties of physical signs and symptoms that it would be strange indeed if we did not often fail to make an accurate diagnosis and use appropriate treatment here. Added to this is the ever-varying condition of the abdominal walls, due to dis-

Digitized by Google

tension and emptiness of the hollow viscera, the engorgement of the solid organs, and the amount of abdominal fat which often comes and goes with remarkable rapidity. These difficulties, from complication of organs and their changeable condition, can hardly be said to exist in the head or chest, but they are somewhat compensated for by the ease with which the abdomen can be manipulated.

To mention a few of our chief difficulties is all that can be accomplished in a short address. First, there are those connected with abdominal aneurysm, on which a book might be written, and an amusing one, for I shall never forget, when preparing an article on this subject, the extraordinary hits and misses in diagnosis which turned up in looking through the scattered literature of the subject. Existing aneurysms had been diagnosed as renal, hepatic, ovarian, and uterine tumours, and conversely nearly every variety of abdominal tumour, and often "no tumour at all," has been diagnosed as aneurysms. My well-known case of aneurysm of the abdominal aorta was at one time treated for lumbago, and was subsequently said to be a fæcal accumulation by a man of great experience. The pelvic department of the abdomen is even more dangerous ground than the abdomen proper. It is here that confusion still reigns, as evidenced by the number of so-called exploratory incisions now made in that region. A good book on the diagnosis of pelvic disease is still wanted, but I doubt if the data for it have yet been obtained. The almost infinite variety of conditions brought about by pregnancy and menstruation almost defy classification, and thus general rules are almost out of the question. For instance, ovarian tumours, simple as their diagnosis generally is, often deceive the most experienced, and we must not rely on general rules even here, or the opened abdomen may possibly stagger our nerves and try our resources. Twice over I have been misled by trusting too much to a resonant note in the flank and a dull abdominal dome, where I discovered our mistake to be due to the fact that the intestines were bound down by adhesions in the lumbar region so closely as to give resonance there in ordinary ascites. Then, again, there are mistakes attaching themselves to pregnancy, about which some experienced accoucheur might give a highly interesting discourse. I recollect a startling case where a patient was about to be admitted to an institution for the removal of an ovarian tumour; but her own doctor thought he would like to do the operation himself, and sent her to me to confirm the diagnosis. Labour pains came on while she was in my waiting-room, and she had just time to reach home in a cab before she was confined. Then, again, there are those trying cases of women who marry late in life, and, being possessed by a longing to have a child, arrive at the menopause and begin to swell visibly. Beware of such women. If you say they are not pregnant they will not believe you, because "they feel a movement which cannot be mistaken." If you for a moment favour their wishes, and incautiously admit it may be so with them, you have staked your reputation on a broken reed, and a day of reckoning lies in store for you some few months hence, "when it does not and will not come off." To be called in under such circumstances is one of the most trying and delicate tasks for a consultant. By a word or a look he may shatter his friend's reputation throughout a wide circle; and yet the truth must be told, either abruptly or—far better—by a gradual undeceiving of the patient's mind.

Far more serious difficulties surround us when we are face to face with ectopic or tubal gestation. A certain diagnosis in many of these cases is impossible without the exploratory incision, and even then the complications may prevent a satisfactory diagnosis—nay, more, I have seen a case of this kind so complicated that a post mortem examination failed to reveal the true state of the case. These are cases of the third order, in which a faulty diagnosis casts no blame on us. Let me give a history of a case illustrating the extreme difficulty or impossibility of arriving at a certain diagnosis. I do so the more readily because I believe the case is unique.

Some years ago the late Mr. John Hope and I saw a patient suffering from intolerable pain in the testes. Both testicles were enlarged, the left as large as a goose's egg, the right slightly smaller. As the enlargement and sufferings increased, especially on the left side, we decided to remove that testicle. On doing so we found a healthy testicle encased in dense concentric layers of suet-like fat about an inch thick. The relief obtained made the patient urgent to have the right testicle removed too, which was done with complete relief. Some months afterwards this man came to me again in a deplorable condition. His body was emaciated, but the abdomen had become enormously enlarged and extremely painful. The abdominal swelling was uniform and dough-like on palpation and absolutely dull on percussion, without any evidence of fluctuation. His chief symptom was a mucous diarrhœa over which remedies had but slight control. He died of exhaustion. On making a post-mortem examination, we found the enlargement was entirely due to the presence of hundreds of fatty tumours scattered throughout the folds of the peritoneum. The mesentery was a mass of them. They varied from the size of a pea to that of an orange, and each was composed of concentric layers of suet-like fat similar to that found around the testicles. The smallest were concentric as distinctly as the largest. The most remarkable developments were in the appendices epiploicæ, each of which extended into the abdomen like a large bunch of grapes studded with fatty nodules. We might, if we had had a similar experience, have divined from the testicular encasements the real cause of the abdominal enlargement; but, lacking this, I think it was impossible to make a sure diagnosis. But I must draw this part of my subject to a close, or I should like to have alluded to the difficulties which surround the medical man who is called to see a patient in the initial stage of any of the acute febrile diseases, especially of infectious diseases. If he speaks of his suspicion too soon he may find he has given needless alarm; if he hesitates too long he may be blamed for not speaking soon enough. A wary outlook, an expectant state of mind, and a knowledge of human nature are all needed to save him from a false position. Lastly, the mistakes which occur in the treatment of disease may be divided into those arising from a false diagnosis and those in which the wrong remedy is used where the diagnosis is correct. I need not say that for the most part a false diagnosis is the cause of most of our mistakes, but this has already been dealt with. With regard to the misapplication of the treatment when the diagnosis is correct, I may say this is often owing to the want of a true appreciation of the temperament and constitution of the patient, whereby we are led to give what is good enough for the disease, but bad for the patient. Let us ever remember, therefore, that we are treating patients as well as diseases, and what may, rigidly speaking, be the right thing for the disease is often the wrong thing for the patient. Take the case of tonics, such as iron and quinine. I know of nothing which has destroyed the confidence of patients, both in medical men and medicines, more frequently than the administration of these remedies to debilitated, anæmic, and phthisical patients when they were quite unable to bear them. How often do we see a patient in the early stage of phthisis suffering from the miseries of dyspepsia added to those of his disease. And yet we find such a patient is being treated by cod liver oil, or iron and quinine phosphates, which only add still further to his misery. Or, again, take the case of anæmia in which the fault lies in a weak and irritable gastric membrane. Nine out of ten of such patients become considerably worse when treated by ferruginous tonics. Or, again, take the case of a patient recovering from an attack of gastric catarrh: to select the exact moment when that membrane will be able to bear a tonic, and decide what tonic to give it, is one of our most difficult problems. In early phthisis, in anæmia, in the exhaustion of gastric catarrh, I rarely venture on any so-called tonic medicine, and prefer to give aids to digestion and sedative correctives until I am well assured the stomach will tolerate such remedies as iron, quinine, or cod-liver oil. I cannot help thinking these misapplications of the right remedy for the disease in unsuitable cases is the secret source of that sceptical attitude which many able men have assumed towards the beneficial action of medicines. In early life they expected too much, and blamed the medicine when really it was its application which was at fault, and so they have lost faith. I, for my part, have an undying, nay, an increasingly vital faith, in the virtue of medicines, and I hope to live to see the day when mankind at large will accord to rational scientific medication the place it undoubtedly deserves to hold in its esteem. Many hints which I could give as the result of thirty years careful study of the action of medicines crowd upon my mind, but I must not trespass further except to say that much depends upon the method of combining our remedies. I believe in combinations; without them we cannot put limitations to the action of our drugs, and we

Digitized by Google

annot guide them to the right spot. One medicine, so to speak, conditions another, and some are complemental to each other. Take digitalis as an example. Do we wish to act upon a weak heart in an anæmic subject we combine it with iron. Do we wish it to act upon the heart where all the organs are engorged from regurgitation in a plethoric subject, we give it combined with mercury and purgatives; or, do we wish to relieve pulmonary congestion arising from the same cause, we combine it with ether and ammonia; or, do we wish it to act on a sluggish kidney, we add some suitable diuretic. We thus, as it were, condition and conduct our remedy to do its work in the right direction. To do otherwise would lead to serious mistakes, and might shake our faith in the power of this mighty drug.

Newcastle-on-Tyne.

PRIMARY DENTITION IN ITS RELATION TO RICKETS.

By GEORGE CARPENTER, M.D. LOND., M.R.C.P.,
PHYSICIAN TO THE OUT-PATIENTS, EVELINA HOSPITAL FOR CHILDREN;
AND
R. DENISON PEDLEY, L.D.S., F.R.C.S. EDIN.,
DENTAL SURGEON TO THE EVELINA HOSPITAL FOR SICK CHILDREN.

THERE is a widespread belief among medical men that the temporary teeth are materially affected in children who are rickety, and as the result of this disorder. In support of this contention extracts from some of the text-books dealing with this disease are given. Thus, one writer says: "Dentition is late and irregular. ..... The teeth themselves are imperfectly formed, their enamel is defective; in a year or two they turn black and break off or fall out."[1] Another writes: "Dentition is much delayed in rickets ..... the enamel of rachitic teeth is bad, rocky, or pitted in its disposition, the teeth are notched or have horizontal ridges, and break away down to the gum, where they appear as black jagged stumps. These conditions are not peculiar to rickets."[2] Another remarks: "Dentition is much delayed and the teeth when cut are deficient in dental enamel, so that they decay rapidly."[3] Another says: "The teeth are late in appearing; the teeth, moreover, are specially apt to decay and become loose."[4] Another observes: "The teeth appear very late, ... while they also rapidly decay or fall out, being deficient in enamel."[5] Others again state that modifications of dentition vary according to the period at which the active phase of rickets becomes manifest. If it be early, there are three ways in which the modifications may occur: 1. The teeth are late in their eruption. 2 The teeth are cut cross—that is, they appear in wrong order. 3. They soon become carious, and are often shed early.[6] In our practice the correctness of these views, in their entirety, has for some time been held in doubt, and with the object of bringing them to the test we have made more careful and extended observations on this subject. For this purpose we have examined the mouths of some 500 children with obvious rickets, and find, as we anticipated, the results are not confirmatory of the prevalent ideas on this subject. Briefly tabulated, these results are as follows: *A*. In the vast majority of patients the teeth are perfect in structure. There is no deficiency of enamel. The teeth do not become loose, and rapidly fall out. There is no special proneness to decay. *B* In those rare cases where the teeth have been found defective a history of inherited syphilis has been obtained. *C*. Dentition is undoubtedly delayed.

The result we have obtained under the heading *C* is then quite in accord with the writers we have quoted, as also with the prevalent opinion, whilst widely differing from them in other respects. Bland Sutton has made the suggestion that the delay is caused by "abnormal thickness of the follicles."[7] By the end of the seventeenth week of fœtal life the dentine is in process of calcification, and about the same time a deposit of enamel commences in the enamel organ. From this time forward the process is a continuous one, so that at birth parts of the crown of the teeth are fully formed, and the course is complete, as regards the crowns, between the third or fourth month after birth. It is still then a doubtful point whether the enamel has received its full impregnation of salts. Of late years it has been recognised by various observers that rickets may commence in utero, and in such instances as these some modifications in structure of the upper parts of the crowns of the teeth might be looked for, as is the case in congenital syphilis. Again, the presence of this disorder at birth, soon after, and up to the third or fourth month, should, on an assumption, bring about some defect of the lower portions of the crowns of the teeth (i.e., near the neck). Following Kassowitz, the earliest indications of rickets are either trifling beading of the rib costo-chondral junctions, or cranio-tabes, or a combination of these. He considers that at least 80 per cent. of children in Vienna under three years of age are rickety. On the question of some trifling beading of the ribs amongst the children of the London poor, we should be prepared to go much further than he does, and say that in a very large out-patient experience we have never yet failed to make out some very slight bossing in this situation in the youngest infants; and that, if this is to be taken as sufficient evidence of rickets, then the disease is nearly ever present in the out-patient room to some extent. A very large number of children must, therefore, be slightly rachitic during the period of the formation of the enamel of the lower half of the crowns of the teeth—i.e., the cervical part.

On the question of cranio-tabes, however, we hold somewhat different views, and consider that congenital syphilis is largely responsible for this condition of affairs.[8] Moreover, in comparison with the beads on the ribs, it is of infrequent occurrence. Given, then, that this beading of the ribs, to however slight an extent present, and seeing also how prevalent this condition is in the out-patient, it would have been expected, if rickets is such a potent factor as the text-books state, that some dental alteration in the shape of enamel scarring would have been detected in a considerable proportion of these cases, yet the contrary has been our experience. We have over and over again watched the teeth-cutting in obviously rickety children—children who have been attending as out-patients for weeks,—yet our observations have not been rewarded by the eruption of pitted and defective enamel: on the contrary, it has appeared to be quite perfect.

It must not be inferred that because a history of syphilis has been observed we consider such teeth syphilitic. Whilst not holding with Parrot that rickets is a syphilitic manifestation, yet in our experience, as doubtless in that of many others, the syphilitic cachexia is when present a very powerful agent in the production of rickets. In a large number of rickety children a syphilitic history can be obtained if inquired for,[9] and the observer is not infrequently startled by the appearance in some such cases of a slight syphilitic rash on the buttocks, anal condylomata, a specific ulcer in the mouth, eye trouble, or what not, in a child who, for all the signs that were present at the time of the first examination, would otherwise have passed as rickety merely. These signs showed that the disease was smouldering on, and that the syphilitic cachexia was underlying the rickety trouble. On this account, therefore, we cannot attach that importance to the heading *B* which we might otherwise have done. What we do say, however, is that it is not proven that rickets is responsible for all the dental troubles that have been laid to its charge; that the association of rickets with carious teeth as between cause and effect is merely an assumption; and that caries does not take place in any case in rickety children to anything like the extent the text-books would lead us to infer. What is wanted is some more extended and definite observations on this interesting point, and not statements which go the round of the various medical books in somewhat different dress, quite unchallenged and accepted as truisms.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON THE RESULT OF EXCISION OF THE KNEE JOINT.

BY HENRY SMITH, F.R.C.S.

A FEW days since, whilst visiting an old pupil in the country, a young man in the garb of a postman was presented to my notice, and with some difficulty I recognised him as one on whom I had performed excision of the knee-joint at King's College Hospital in 1882. On examining the limb I found that it was perfectly straight, and thoroughly firm at the seat of incision. There was so little shortening that it was hardly perceptible, and the calf was well-developed. He informed me that he was following the occupation of a country postman, and sometimes would walk twenty miles in the day. He did not use any stick. It appears that he was fourteen years of age when the operation was performed.

This case is interesting and valuable as showing the utility of a limb after excision, and particularly so considering the nature of the man's occupation. It has occurred to me, I am happy to say, to meet with several cases where I have been able to test the utility of a limb years after excision of the knee, and I have been astonished with the results observed; but I have rarely met with a more satisfactory case than the one related, although amongst others I may refer to two instances occasionally seen by me in the neighbourhood of my country residence, and both of which were operated on some years since in King's College Hospital. In the one the patient is a fine tall woman, who is fulfilling the duties of lady's maid and walks without a halt; in the other the patient is a fly driver, who jumps up and down from his box with great facility and walks with scarcely any limping. Those who take an interest in this subject will agree with me that such cases as these, observed years after the operation, are especially valuable, and the more so when we bear in mind the opposition which was experienced by those of us who persisted in giving it a fair trial, although it was denounced as "mountebank surgery," and an eminent lecturer publicly stated that the result of removing the knee-joint would be merely the retention of a limb only "fit for a flail."

Wimpole street, W.

CASE OF PLACENTA PRÆVIA.

BY JAMES GILROY, M.B.

ON Feb. 17th, about 10.30 P.M., I was requested to visit Mrs. P——, residing some miles distant. The facts of the case, as given by the patient, were that about 8 P.M. that evening she had been suddenly seized with hæmorrhage, that she was pregnant, and expected her confinement early next April. The patient is a young married woman with a family of three children, and never had anything out of the way, to her knowledge, in previous confinements. On examination per vaginam I found the flow of blood had ceased, and that no uterine contractions were taking place. The os admitted the point of the finger easily enough, and the membranes appeared to be intact. As the patient said she thought the bleeding might have resulted from a mental shock she sustained that day, and had no pain whatever, and the bleeding apparently ceased, I left her, enjoining rest in bed, a light diet, and instructing her to send at once for assistance if the bleeding returned. She had no nurse to whom I could confide the operation of plugging in case of sudden emergency arising. I saw her again on the 19th, when she informed me there had been no return of the bleeding, and she still kept her bed. I heard no more of the case until Feb. 23rd, when I was hastily summoned. I found the patient bleeding copiously, with an undilated os, from which, the moment I attempted to dilate, blood issued in a perfect torrent. On sweeping the circumference of the arc of the circle denoted by the presenting part, evidently the head of the child, I came upon a boggy projecting part, which gave with sufficient clearness a guide as to the nature of the case. I proceeded to dilate the os with my fingers as speedily as I could, and succeeded in inserting my hand, and although only a matter of a few minutes, the bed was drenched with blood, which dilatation rendered alarming in character and amount. I seized a hand first in attempting version, but, feeling sure as to the thumb, got past that and brought down the foot. The rest was easy, the head following suit readily, and not, as in a previous somewhat similar case of placenta prævia, getting hitched at the promontory of the sacrum. The patient has done well since. The infant survived its birth only seven days. A curious point about the placenta I wish to record is that it was quadrilateral (perhaps lozenge-shaped would convey more correctly what I mean) in shape and the cord joined it at one corner.

Waterbeck, Dumfriesshire.

TWO CASES OF CONCUSSION OF THE SPINAL CORD.

BY F. LE GROS CLARK, F.R.S.,
CONSULTING SURGEON TO ST. THOMAS'S HOSPITAL.
Reported by Herbert A. Lawton, M.D.

AS a further contribution to the literature of concussion of the spinal cord, I think the following cases, which occurred in the practice of Mr. Le Gros Clark (who has kindly given permission for their publication), worth recording. I have copied them from my case-book notes made during the winter session 1871–72, when acting as dresser.

W. C——, aged twenty, labourer, residing in Lambeth, was admitted into Albert Ward on Dec. 13th, 1871, suffering from an injury to the spine. The patient states that while employed in unloading a barge he had to carry a basket weighing 1 cwt. along a plank 28 ft. in length from the barge to the wharf. At the end of the plank was a ladder, up which he had to go. He had got his foot on the first step, and was proceeding to ascend the second, when he slipped and fell across the plank, the edge of which struck against the small of his back. At the same time he let go the basket, which fell on his abdomen, thus jamming him between the plank and the basket. He was prevented from falling into the river. He was unconscious for a short time. On admission, about one hour after the accident, he was found to have sustained a fracture of the spinous process of the fourth lumbar vertebra, with depression. The lower extremities were cold and paralysed. As he could not pass his urine, a catheter was introduced into the bladder.—Dec. 14th: The patient slept but little last night. He complains of shooting pains in the back. There is complete loss of sensation from two and a half to three inches above the umbilicus, extending all down the lower extremities. He has no control over bladder or rectum. Catheter to be passed three times a day. On going round late at night this patient was found to be lying on his left side. His bladder had emptied itself, he being unconscious of it.—15th: This morning he passed his urine consciously. There is some return of sensation about flanks and umbilicus.—19th: He has recovered sensation over the whole abdomen and lower extremities, also control over the bladder. Eats well, sleeps well. He attempted to leave the hospital last night.—27th: Gets about now. Sensation and motion of lower extremities perfect. Discharged cured.

R. P——, aged forty-nine, clerk, admitted into Albert Ward on March 10th, 1872, at 12.15 A.M. About three hours prior to admission, while under the influence of alcohol, he slipped down a flight of stone doorsteps. On admission, the lower extremities were cold and sensation considerably diminished. He was very tender in the lumbar region.—March 11th: Has dozed during the night. Sensation has nearly returned. No retention of urine. Cough troublesome. The following mixture was ordered to be taken three times a day:—One drachm of compound tincture of camphor, two drachms of liquor ammoniæ acetatis, one drachm of mistura acaciæ, to an ounce of water. March 13th: Sensation has now quite returned. Sleeps fairly. Cough better.—21st: Doing well. To get up.—25th: Up and walking about.—28th: Discharged cured.

CASE OF BALANITIS IN A CHILD AGED THREE YEARS.

By J. W. MARTIN, M.D., F.R.C.P. EDIN.

ON Feb. 10th, 1891, I was called to a child aged three years and a quarter, suffering from some affection of the genitals. The child has a left inguinal hernia, for which it wears a truss. He had not been vaccinated on that account. His left arm had been fractured on two occasions. The anterior fontanelle is not completely closed. The mother stated he had slept with the truss on for two nights. On Tuesday, March 8th, the child was pained and "swelled." On Wednesday he had difficulty in passing urine. He was restless at night, complained of thirst, and had no appetite. His head and face were swollen. A quantity of thick milk-white matter came away from the penis, and he could make water; after this the symptoms began to lessen. On examining the penis I found the thick whitish discharge oozing out of the point of the penis, the glans was swollen, and the skin over it reddened. The prepuce was seen to be red and inflamed. On inquiry I ascertained that a relative, who suffers from a discharge owing to chronic cystitis, had been in the habit of nursing the child when he came in, and being dressed as children of such years generally are, the child's penis must have come in contact with some of the discharge, and the infection have been set up in this way. There was no other reason to account for it. Any dirty discharge will set up similar inflammation in a young subject, not to mention gonorrhœa. With local and general treatment the balanitis soon got better, the only complication being an attack of vomiting and purging one night.

The case seems to me worthy of being placed on record because of its rarity, and as a warning to those having any chronic discharge not to nurse or fondle infants.

LONDON HOSPITAL.

PERIOSTITIS OCCURRING AS A SEQUELA OF ENTERIC FEVER.

(Under the care of Dr. STEPHEN MACKENZIE.)

DR. MACKENZIE remarks, with regard to this case, that the occurrence of periostitis, as a sequel to enteric fever, is not common in his experience; but the disease is probably less infrequent than is generally believed. It is not alluded to in several standard text-books, but is mentioned by Bristowe, and by Cayley in Fowler's "Dictionary of Practical Medicine." Sir James Paget appears to have been the first to draw attention to the lesion, and cases have been recorded by Messrs. Hayward, Mackay, Jackson, H. W. King, Afflick, Gostling, and others, and M. Routier has written on the subject. Periostitis after enteric fever occurs most frequently in young persons. The most common situation is on the bones of the extremities, especially the tibia, where it sometimes occurs symmetrically; but it may occur on the ribs and sternum. It usually occurs during convalescence, when, as Sir James Paget says, the patient is "well of his fever"; but, as Dr. Afflick has shown, it may take place during the pyrexial period. Contrary to what happened in the present instance, it usually suppurates, and often causes necrosis of the subjacent bone, and in rare instances occurs in a chronic form. With regard to its causation, M. Routier attributes it to injury in all cases, though, as pointed out by some observers, it would probably, if this were the case, be present in other fevers followed by exhaustion and devitalisation of the tissues. The more likely explanation is that suggested by Sir James Paget,[1] that it is due to some morbid material remaining in the blood and affecting only certain tissues. To quote his words, "After all the signs of typhoid fever have passed away, when the convalescence is established, and all the waste and damage of the disease are being repaired—while thus, in respect of general nutrition, the health might be deemed above its average, we may find an acute inflammation of one portion of the periosteum of one bone. It is surely an evidence that that one portion was the only portion of the body in and with which the something in the blood could generate disease. It seems the more evident in the fact that sometimes the periostitis has appeared symmetrically on both the tibiæ. The two portions of periosteum symmetrically placed were identical in composition, as symmetrical pieces of the body often are; therefore both were similarly disturbed—no other part being exactly like them no other was disturbed. In all the body nothing was susceptible of the disease except these two pieces." Syphilis, in which *par excellence* periostitis is usually encountered, has been called by Mr. Hutchinson, "an exanthem long drawn out," and it is interesting that in the most protracted of the specific fevers of this country—enteric fever—periostitis is occasionally met with. Moreover, whilst in syphilis periostitis is usually a tertiary phenomenon, yet it occasionally occurs in the secondary and febrile period. The parallelism is therefore close. For the notes of this case we are indebted to Dr. J. H. Sequeira.

P. L——, aged sixteen, dressmaker, was admitted to the London Hospital on Sept. 10th, 1891. She was then complaining of pains in the back, stomach, and head. The temperature on admission was 102·4°. There was no history of any previous illness. One brother, eleven years old, suffers from chorea. The rest of the family are healthy. The case proved to be a characteristic example of enteric fever. Successive crops of spots appeared, and the stools were yellow and fluid. The evening temperatures reached 104° on several occasions. On Sept. 23rd the temperature began to show large morning remissions, but was not persistently normal until after Oct. 16th. On Oct. 26th a swelling was noticed on the right ulna, near the wrist. The swelling was tender, hot, and red, and was connected with the bone. Evaporating lead lotions were applied, and the tenderness and heat had disappeared by Oct. 31st, but some thickening of the bone persisted for a week longer.

BRISTOL GENERAL HOSPITAL.

MULTIPLE TUBERCULAR CEREBRAL TUMOURS; CONVULSIONS; TREPHINING OVER MOTOR AREA.

(Under the care of Mr. NELSON C. DOBSON.)

THIS case illustrates a condition of some rarity, the presence of a tubercular growth in the motor area of the brain, which was sufficient to cause symptoms of so much importance that it was localised, and an attempt made to remove it. There were several other tubercular deposits within the skull, but they did not give rise to symptoms indicating their presence. Dr. Hale White, in writing of the cases of tubercular character amongst the series of cerebral tumours collected by him, says that not more than three of the forty-five were likely to be benefited by operation, and they were accompanied by tubercular disease of other organs. There are now several recorded cases in which, although the tumour was not found at the operation, or its removal was incomplete, great relief was experienced as the result of the diminished pressure. We have published a case which was under the care of Mr. F. A. Heath, which shows this in a marked degree.[2] There is no doubt the growth found at the edge of the trephine opening was the discharging lesion which caused the unilateral convulsions. Even if the trephine opening had exposed it, and it had been removed, the larger growth in the opposite corpus striatum might have proved fatal. As it was, headache never recurred after the relief of the intracranial pressure by trephining; and had the wound not become septic the patient might by this relief have been materially

[1] THE LANCET, vol. ii. 1887, p. 1001: Neale's "Digest," third edition. By a printer's error it is given as vol. ii. 1889, and Dr. Mackenzie wishes to thank Dr. Neale for the correction.

[2] THE LANCET, vol. i. 1888.

Digitized by Google

benefited, and perhaps the tubercular growths might have become quiescent. The fatal meningitis seems to have set in after the escape of the cerebro-spinal fluid on the 5th of April. For the notes of the case we are indebted to Mr. Charles A. Morton, registrar.

A. S——, aged eighteen, was admitted into the hospital on Feb. 1st, 1892, with the following history:—For five years she had been subject to czæna. Ten weeks before admission she began to suffer from pain across the forehead, extending over the back of the head and down the neck. Shortly after the headache began she commenced to vomit frequently and quite irrespective of food. After a few weeks the headache and vomiting became less marked, only occurring every other day. On the alternate days she seemed quite well. Six weeks before admission she began to suffer from weekly attacks of twitching in the left upper limb, beginning in the thumb and first finger. This has always been preceded by a feeling as if the parts were too large, beginning in the thumb only and then spreading up the arm to the shoulder. During the last two attacks it has, however, begun in the fingers also. During the last fortnight, when this aura has come on in connexion with the convulsive movements of the arm, there has been a sensation in the left side of the tongue and inside of the cheek and gums on the same side, as if she had had "too hot tea in her mouth," and yet she said it was not a numb feeling, and she could not describe it other than as a "lumpy feeling." The aura in the tongue always followed the aura in the arm. There was never any convulsive movement of the face noticed. The convulsive movements were limited to the left arm until Feb. 4th. They were never followed by any paresis in the arm.

On Feb. 4th (after admission) Mr. Morton was standing by the bedside, after an ophthalmoscopic examination, when she called his attention to her left arm, which she said felt numb. Clonic spasm was then present in the arm, then the limb became rigid and drawn up, quickly followed by general rigidity, and then clonic spasm lasting about a minute, accompanied by coma and followed by much lividity and pallor and feebleness of pulse. This condition of cardiac and respiratory failure quickly passed off, and consciousness soon returned, so that she knew when spoken to, and said "Yes," but a quarter of an hour after she did not recognise her relatives. Before an hour had elapsed, however, she knew them again. This was the only attack of general convulsions she had during the course of her illness.

Three weeks after her illness began she commenced to see double. This lasted four weeks, and was constant. During this time she is said to have squinted with the left eye. Her sight began to fail six weeks before admission, and at times even perception of light failed. There had been no otorrhœa. There was a distinct history of one rigor whilst she was sitting by the fire at the beginning of her illness. She had been up and about for some time before admission.

On admission it was noted that she looked well, and was free from headache and vomiting. There was, however, intense double optic neuritis. The discs were so swollen that the surface was seen with a +5, and there was great hurrying and bending of the vessels, and numerous striated nerve-fibre hæmorrhages around. In the right eye, upwards and inwards, not far from the disc, was a smooth retinal elevation, the vessels on which were seen with a +6. In the macula were numerous glistening white spots, and below large patches of retinal effusion and hæmorrhage. Vision: right eye, $\frac{5}{12}$ and J. 4; left, $\frac{5}{18}$, J. 10. There was no loss of power in the left hand or left side of face, and no anæsthesia, analgesia, or thermanæsthesia; no deviation of tongue and no ocular paralysis; pulse 112, small but regular; respiration 24–28. She could walk about very well and her memory was very good. There was no tenderness over any part of the skull or frontal sinuses. The nose was examined by Dr. Baron, who reported that both sides were covered with thick scabs which prevented further examination until removal. Her lungs and urine were normal. It was considered almost certain that there was a gross lesion involving the arm and face centre, and the history of ozæna, with a rigor at the beginning of her illness, pointed to cerebral abscess, probably secondary to frontal sinus mischief, and therefore in the frontal lobe, which had after some weeks extended backwards, and had begun to irritate the arm and face centres. The history of czæna and rigor seemed to make this more probably the explanation of the symptoms than cerebral tumour, which, however, was recognised as a very possible cause. Her temperature was normal, but this of course was not more in favour of one than the other. It was decided at a consultation, as the girl seemed so well, not to explore at that time.

On Feb. 9th, at noon, she had a sensation as if the left thumb were too large, and twitching of the thumb, lasting a few minutes. This time the spasm was simply in the thumb, and did not consist in approximation of the thumb and forefinger, and it did not spread up the arm; very shortly after this attack she had the curious feeling in the left side of the tongue and inside of the cheek, lasting ten minutes. Directly after this Mr. Morton saw her, and noticed the mouth slightly drawn to the right, and marked powerlessness of the left angle. She could completely close both eyes. There was no ocular deviation or paresis, no anæsthesia of thumb, hand, or left side of face, and her mental condition seemed unimpaired. During the month from Feb. 9th to March 8th she had three attacks of headache only, but they were severe, and she never vomited. They were on the 15th, 18th, and 29th of February. She seemed much inclined to sleep, but was always quite sensible when awake, until March 2nd, when she became rather noisy and excited, and had to be removed to a private ward. But on the following day she became quiet and rational again, and on March 7th she returned to the general ward. At this time she was rather drowsy, and headache was troublesome. On Feb. 16th the eyes were again examined ophthalmoscopically and very numerous flame-shaped hæmorrhages were seen around the disc, extending far into the periphery in the left eye. These had not been seen on the previous examination, and this hæmorrhagic condition was on this second examination much more marked in the left than in the right eye, where the hæmorrhages were not numerous, and were confined to the neighbourhood of the disc. The glistening spots in the right and the swelling of the discs remained the same. The macula had also become surrounded by a diffuse whiteness. By the 29th of February vision was reduced to rather dull perception of light in both eyes. With the exception of one evening rise to 100°, the temperature up to March 10th was normal. Only once after syringing had there been any purulent discharge from the nose.

In the evening of March 9th headache returned, and between 3 A.M. and 6 A.M. she was very excited, sitting up in bed and singing. At 6 A.M. she became unconscious, and remained so until 8 A.M. After return of consciousness she felt sick but did not vomit, and her memory was impaired. It was now decided to trephine over her arm and face centre and explore the brain for abscess and tumour, and it was thought that even if one was not discovered, the intracranial pressure might be relieved. The head having been shaved and thoroughly carbolised, the fissure of Rolando was marked out according to Reid's lines, and a point in the middle of the fissure marked on the bone with a bradawl. A flap was turned down and the bradawl puncture sought for, but not found. However, Mr. Dobson was sure of its exact position, and the skull was trephined there. On removal of the crown of bone the dura mater bulged much into the wound, and on removal of this the brain bulged into the opening still more, so as to protrude slightly beyond the level of the outer surface of the skull; it appeared normal. The brain was explored in all directions with an exploring syringe with needle three inches long. The operation was thoroughly antiseptic. A drainage-tube was placed under the flap, projecting at the upper angles. She took the chloroform for the half-hour very well.

The patient lived a month after the operation. During this time she had no headache and remained perfectly rational and quiet until a few days before her death. Unfortunately the wound did not remain aseptic, and after much œdematous swelling of the scalp and face a hernia cerebri formed, and after a time septic meningitis followed. Hemiplegia began to develop the day after the trephining on the opposite side, beginning in the hand and the left angle of the mouth, and then involving the whole of the upper and lower limbs, and later on becoming associated with complete analgesia of the left upper and lower limbs and side of body, and complete anæsthesia in lower limbs, and great impairment of sensibility in the upper. The fundus hæmorrhages nearly cleared up, and there was very slight diminution in the neuritis in the right towards the end. On one occasion she discharged a small quantity of thick

Digitized by Google

greenish pus from the nose. On April 5th she discharged large quantities of watery fluid from the cranial opening. The hernia cerebri was by this time very large, and had pushed open the flap of skin. From the time of this discharge of cerebro-spinal fluid her mental condition altered, and she became less conscious of things about her. The discharge was only noticed for twelve hours. No doubt the lateral ventricle had been opened by the rapidly increasing cerebral softening and hernia cerebri. After this she quickly became comatose, and a fine tremor set in in the right (the non-paralysed) side, and continued in the arm with the addition of more convulsive movements, but ceased in the leg before death, which took place on the 10th. During the last day she vomited everything. The first serious rise of temperature after the operation was on the third day, to 103°; after this it continued to range between 101° in the morning and 104° at night daily for a fortnight; it then dropped to 100° in the morning, but still rose to 104° at night for another week; then for some days became normal in the morning, but 105° at night; and then on and after the fifth day, when she discharged the cerebro-spinal fluid, the temperature ceased to fall in the morning, and was usually between 105° and 106°; and on the eighth and ninth reached 107°, but quickly fell again lower than it had averaged before during these days. During the last twelve hours it three times reached 106°. On the ninth the pulse was 160, respiration 80; breathing Cheyne-Stokes the night before.

The post-mortem examination of the brain.—The cerebral cortex above the hernia (which was the size of a small orange) was seen to fall in, and the frontal lobe to be much shrunken. On cutting into the brain it was apparent that a great part of the middle third of the hemisphere had disappeared into the hernia, and the rest was represented by a mass of red, soft, almost liquid tissue, and through this the lateral ventricle was opened. This softened brain tissue was adherent to the dura mater all round the trephine opening; and after the brain had been cut up a nodule of firm tubercle the size of a half-crown was discovered immediately under the dura mater in this soft brain matter, where they were adherent, just at the edge of the trephine opening so that the edge of the growth met the edge of the opening), either in front of or behind it, but it was not possible to say which. There were two other small nodules of tubercular growth elsewhere in this hemisphere, away from the motor area. The lateral ventricles were quite empty. In the caudate nucleus of the left side (the opposite side to the cortex growth just described), slightly projecting into the ventricle, and exposed on its inner aspect by a median section through the brain, was a nodulated firm yellow tubercular growth, looking, as it projected into the ventricle, about the size of a walnut, but it only extended a very short distance into the corpus striatum. There was also a small quite superficial nodule the size of a shilling just under the surface in the left superior parietal lobule, one inch from the upper and inner margin of the hemisphere, and just behind the ascending parietal convolution. There was also one the same size in the posterior part of the left occipital lobe. All these growths were typically tubercular. There was purulent meningitis of the right side of the vertex and the base. The patch of raised retina in the right eye proved to be a tubercular growth seven millimetres in diameter. The upper part of both lungs contained numerous miliary tubercles. The bronchial glands were not caseous. All the other organs were healthy, and there were no miliary tubercles seen in them.

METROPOLITAN PUBLIC GARDENS ASSOCIATION.—It was announced at the last monthly meeting of this Association that the old burial grounds, Hackney-road, and De Beauvoir-square, Kingsland-road, would shortly be opened for the public use; that the Association was adapting for recreation purposes the churchyards at Spitalfields and St. Ann's, Soho; and that satisfactory arrangements had been made with Lord Calthorpe with regard to the open space in front of Duncan-terrace, Islington. It was decided to take steps for the acquisition of St. Thomas's-square, Hackney, which the local authorities were willing to maintain, and also to take charge during the summer months of the churchyards of St. Katherine Coleman and St. Dunstan's-in-the-East.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Adjourned Debate on Renal Dropsy.

AN ordinary meeting of this Society took place on May 11th, the President, Sir Andrew Clark, in the chair.

Dr. DOUGLAS POWELL, in reopening the discussion on Dr. Dickinson's paper, said he thought it would clear the ground if speakers declared at once whether or not they accepted the statement put forward by Dr. Pye-Smith, in which, so far as he personally was concerned, he heartily concurred—namely, that the late dropsy of renal disease had no essential connexion with the kidney mischief, but was the direct consequence of heart failure. In interstitial nephritis the diseased kidney underwent gradual destruction, and by and by uræmic phenomena made their appearance. But this variety of kidney disease was marked by a singular absence of dropsy, though should the patient survive the uræmic accidents, and should the case go on to the bitter end, then later on in the disease dropsy came on, but only as an indication of and associated with heart failure. He pointed out that this form of kidney disease was characterised throughout by the so-called high-tension pulse from the very earliest stage. This condition of the pulse persisted until the later stages of the disease, and it was only quite at the end, that passive œdema supervened. Then, still later, œdema of the lungs, anginal complications, and gradually increasing dropsy closed the scene. In tubular nephritis the dropsical phenomena were among the early symptoms, diminishing as the case went on, just as the signs of arterial tension made their appearance, and as the heart underwent hypertrophy. He had indeed noted cases of acute nephritis not associated with dropsy, but there had invariably been either vomiting or diarrhœa, or other flux, compensating for the absence of renal secretion, and thus the dropsy had been warded off. He strongly inclined to the belief that the high-tension pulse of kidney disease had really nothing to do with the production of the dropsy. On the contrary, he had remarked increase of arterial tension was often associated with diminished dropsy. On the whole, he did not consider that the arterial tension met with in kidney disease was greater than that met with in acute diseases of all kinds associated with febrile symptoms—as, for instance, acute gout, peritonitis, &c., though in this case the arterioles were relaxed. He regarded the cardio-vascular changes as compensatory, as an attempt to carry on the renal secretion under difficulties, as called forth by the requirements of the kidney function in the direction of increased pressure. Then, again, the high-tension pulse was by no means necessarily associated with renal disease, being met with in other conditions, as in fevers, when it was not accompanied by dropsy. What, then, was the cause of renal dropsy? The author had mentioned two possible or probable causes: one of transudation through the walls of the vessels under pressure or increased osmosis, the other a kind of secretory power possessed by the capillaries, which he confessed he did not quite understand. Dr. Pye-Smith had suggested a fourth cause, that the dropsy of acute nephritis was of the nature of an inflammatory exudation. He could not admit pressure as a direct cause of dropsy in renal disease, seeing that during the period of highest tension dropsy was not present. In heart cases the patient was often greatly distressed, yet there was no dropsy for some reason. When it did develop great relief followed. He thought that possibly osmosis did to some extent answer the question. Most of them would agree that the dropsy of renal disease was osmotic, and intended to compensate for deficient kidney secretion, increasing in proportion to the renal insufficiency, and decreasing as it was re-established. There was nothing very special about this phenomenon, for it was constantly going on in health. He did not see how Dr. Pye-Smith could substantiate his view as to the inflammatory character of the œdema in acute nephritis. There was no clinical evidence to support it, and the characters of the fluid were quite distinct. He mentioned the case of a young woman of twenty-five who had had scarlet fever in early life, with dropsy then. Two years before admission she was undoubtedly albuminuric, with hæmor-

Digitized by Google

rhages, cardiac hypertrophy, &c. Her pulse exhibited the condition of high arterial tension to perfection, and in some tracings even when the radial artery was completely arrested the pulse tracing was still perceptible below the level of obstruction.

Dr. BROADBENT said he was prepared to go a long way with the author in the explanations which he had suggested as to the causation of renal dropsy. The observation of renal and cardiac dropsy showed so many points of resemblance as to suggest that there must be a similarity of causation. If, therefore, they admitted the hydraulic causation of cardiac dropsy, some hydraulic cause must be sought for in dropsy of renal origin. The fact that renal dropsy came chiefly in the lower extremities tended to support the view that it must resemble cardiac dropsy. A patient lying in bed with renal disease did not get dropsy, but it appeared so soon as he got up. The conclusions to be drawn from these phenomena were so obvious as to gainsay the suggestion that renal dropsy was ever or in any degree inflammatory. He believed that the obstruction was situated at first in the capillary system and not primarily in the arterioles. He well remembered this idea as having been suggested by the celebrated Dr. Payne when Dr. Johnson brought forward his hypothesis. It by no means told against his great discovery that the site of the obstruction was shifted, and was made primarily arterial and secondarily capillary. He was ready to admit that the additional obstruction which gave rise to the dropsy in renal disease was resident in the capillaries, and that something in the blood was the cause of the increased resistance, and thus caused the exudation. The pathological phenomena of tubular nephritis were exceedingly interesting. In the heart the phenomena were those of acute dilatation. There was from the first mechanical evidence of arterial tension when the pulse was not exactly of the same kind to give that impression, and with the idea in one's mind of capillary obstruction, the character of the pulse in the first instance was suggestive of obstruction beyond the arterioles and not due to arterial contraction. Then the immediate prognosis of acute renal dropsy could always be determined by the development of the ordinary signs of high arterial tension: the full vessel, the modification of the heart sound, the prolonging of the first sound, the extended second sound. If in the course of a week or two these indications did not develop, the prognosis of acute renal dropsy became serious, and many times one had seen these cases linger on indefinitely, and one had been able to anticipate this course by failure of this high arterial tension. With regard to the dropsy of old-standing chronic Bright's disease, undoubtedly that was a dropsy due to cardiac failure, and not to any increase of blood pressure or to the renal changes. He had frequently witnessed the supervention of dropsy and albuminuria late in the history o fcontracted granular kidney after an acute attack of acute tubular nephritis, when the whole affair had been the giving way of the left ventricle. In Dr. Dickinson's explanation he thought they had the most probable explanation of renal dropsy yet formulated. Without accepting it definitely, he was greatly disposed to regard it as in all probability the correct explanation.

Dr. SANSOM said the question before them was whether the phenomena of cardiac and renal dropsy could be explained by dynamic causes or not. The discussion had gone far to answer the question in the affirmative. From what he had seen and observed he felt compelled to differ from that conclusion, and he thought they must look elsewhere for the chief, the determining factor. The question of arterial tension was much more complicated than one might have been tempted to think from the observations that had been made. What did they mean, after all, by a high arterial tension? In the first place, he thought that these factors might be dissociated, and were commonly dissociated; that is to say, the cardiac and the vascular phenomena. There might be increased cardiac activity without arterial contraction, and *vice versâ*. He would assume the arterioles to be relaxed while the cardiac portion of the circulation was contracted. That occurred in the early stages of fevers, when, with a strongly contracting heart, there were relaxed arterioles and a dicrotous pulse. It would not be correct in such cases to say there was low arterial tension, though, judging solely from the pulse, one might be tempted to say so. It was a pulse of high tension, for the blood pressure at a given moment was greatly above the normal. Conversely they might have very contracted arterioles with feeble cardiac action, giving a small pulse presenting the characters of high tension. He must therefore plead for a reconstruction of the terminology. High arterial tension might exist not only in conditions of health, but even in aortic regurgitation. The difference was that in chronic renal disease the high tension was prolonged. It was sufficient for his purpose to say that the cardiac phenomena and the vascular phenomena might not go hand in hand. That fact, he thought, had a considerable bearing on the question of the dynamic causation of dropsy, whether renal or cardiac. Moreover, the tension, even in chronic renal disease, was by no means a constant quantity. Most of them would agree that there were occasions when the tension underwent great alterations, as, for instance, in the course of an inter-current attack of some febrile disorder, without any consequent alteration in the amount of the dropsy. On the contrary, the dropsy would often increase during the period of low tension, and decrease when the high tension was restored. He did not think, therefore, that it was possible to establish any constant ratio between the cardio-vascular phenomena, so far as the production of dropsy was concerned. He could not agree with the view suggested by Dr. Pye-Smith in this respect. Dr. Pye-Smith had stated that the arterioles could not be concerned in affecting the onward current of the circulation, for they were always repressive and never onward forces in the circulation. That, however, was after all a matter of degree. With contracted arterioles and a weak heart they got a small supply of blood to the capillaries. He had seen evidences of this in curarised frogs going on to extreme contraction of the arterioles and obliteration of the capillaries. The action was repressive or exciting, according to the relationship between the heart and the vessels. Whether the obstruction was in the arterioles or in the capillaries, he could not conceive how the dropsy could be attributed to the escape of the fluid elements from the capillaries or to any hypothetical relation between the capillaries and the surrounding tissues. When they saw such immediate results as followed the inhalation of nitrite of amyl or other agents that relaxed the arterial walls, it showed that the major and by far the greater source of the cause of obstruction must be in the arterioles, and not near their junction with the capillaries. That seemed to him to be incontrovertible. Having said this much in the direction of destructive criticism, he would turn to constructive observations. What might the cause of the dropsy be if not dynamic? He was surprised that nothing had been said in the discussion of the interesting and valuable researches of the late Dr. Wooldridge, who had shown what remarkable effects followed the injection of toxines into the blood. Dr. Wooldridge had demonstrated that dropsy would not occur in dynamic conditions of the blood very carefully brought about, unless some small amount of lymph products were injected into the blood. So soon as that was done the dropsy followed. He urged that it was not difficult in renal disease to assume that reabsorption was likely to take place in view of an impeded excretion, and the effect was transudation, as observed by actual experiment. Again, in cardiac disease it was not a matter of conjecture. He had himself seen plugging of the subclavian vein close to the duct followed by extreme general dropsy and gradual recovery. It was borne out occasionally by clinical experience, and still more so the probability that, not for one moment doubting that dynamic causes had their *rôles*, yet that auto-intoxication certainly was not without importance in the production of both renal and cardiac dropsy.

Dr. HAIG pointed out that in everybody and every day there were physiological causes at work which would have for effect to determine the presence in the blood or tissues of an excess of water which might be unable to pass out. That condition was the contraction of the arterioles, and in a paper which he had recently read before the Society he had shown that the most frequent cause of this contraction was the presence of uric acid. He pointed out that in renal incompetency the surplus water might be got rid of by cutaneous means or by the lungs, but when the arterioles were contracted, the water could not get out in either direction. Dilate the arterioles and it passed freely in every direction. He showed a diagram tabulating the results obtained by the use of drugs which contracted the arterioles, and their effect was the same as that of uric acid. As the blood pressure rose the excretion of urine augmented, but when the blood pressure reached its highest point the secre-

Digitized by Google

tion of urine diminished and reached its lowest point. Later on, as the blood pressure fell to or below normal, the excretion of urine rose again. Those were the effects observed under erythrophleum, and they were identical with those in uric acid. This point was very well seen in the uric acid headache. During an attack the excretion of urine fell as low as 30cc. Then if they cleared the uric acid away the secretion rapidly rose to 200 or 300cc. in the same period of time. The author mentioned that dropsy did not follow obstructive suppression of urine, but in that condition the escape of the water was only checked in one direction, consequently no accumulation took place in the blood. Acute nephritis was a totally different condition. There was always contraction of the arterioles and excess of water in the blood, the escape of which from the body was plugged in every direction. The dropsy in this case resulted from this accumulation. In the uric acid headache the eyelids had been noticed to become puffy, amounting to almost a beginning of dropsy. There were times when an excess of uric acid leading to contraction of the arterioles and an accumulation of water in the blood took place in everyone. It had been objected to his theory of an alkaline wave that it resulted from the breakfast; but as a matter of fact it occurred before that meal, and was accompanied by scanty urine, which secretion was restored by a small dose of opium, which restored the circulation.

Dr. LAZARUS BARLOW observed that physiological experiments could hardly be adduced in support of pathological facts, and the question of asphyxia, as propounded by Dr. Johnson, hardly seemed to him to support the theory associated with his name. The increase of blood pressure in asphyxia was not to cut off venous blood from the lungs, but was the expression of the need of increased respiration from the medulla. He thought the more or less rival theories of the author and Dr. Johnson were perhaps not wholly irreconcilable. There was one fact well known in pathology—viz., the series of phenomena in inflammation. Though he wished firmly to disclaim that the dropsy of renal disease had anything to do with inflammation, yet it was only reasonable to suppose that something of the same kind might hold good in the two cases. There were deleterious substances circulating in the blood, and these might have some effect on the capillaries through which they passed. It must, however, be brought about in a reflex manner, and the afferent termination of the reflex apparatus was situated in the tissues to which the blood was supplied. Secondly, the deleterious substances in the blood might set up a constrictive action in the arterioles, so that the opposite views of the hypertrophied arterioles and the action of the capillaries might in this way somewhat coincide. In the first place the deleterious material came into contact with the capillary walls, partly producing dropsy by damage to the walls, and also by a certain amount of vital secreting power, which could not in this minor degree be annulled. Lastly, by the slowing of the flow through the capillaries due to arterial contraction: the flow of lymph increased with the increase of blood pressure; yet it was quite possible that with an increase of positive pressure inside the capillary bloodvessels and a lengthened stay in the capillaries transudation might be increased. The contraction of the arterioles might pass off as in puerperal eclampsia, the tension fell, and the patient recovered. This was shown very clearly in a case at St. George's Hospital, in which the pressure and the pulse returned to normal after a stay in the hospital. After long-continued pressure the cardio-vascular changes came to pass, and the pressure was raised in the renal artery, followed by an increase in the flow of urine; hence a getting-rid of deleterious products, and some possibility of repair of the damaged capillary walls. Lastly, the cardiac failure set in. It was not, however, merely a question of cardiac failure. It was rather a combination of this with the other causes. The fact that erysipelas was common in the later stage of renal dropsy, and rare in cardiac dropsy, showed that there was some essential difference in the nature of the two conditions.

Dr. DICKINSON, in reply, said that Dr. Johnson's remarks were largely based on a misconception of the views contained in his paper. As a matter of fact, there was so much agreement of views that he had hoped to receive his support on this occasion. His attention had been excited by observing the enormous effect of differences of pressure on two sides of an animal membrane largely in excess of any effect that could be produced by osmosis. Many of the remarks attributed to him by Dr. Johnson in respect of the *rôle* of the capillaries had not been uttered by him. Whether the arterial thickening came as Dr. Johnson had described remained to be discussed. Let them assume that he was arguing at a time anterior to the thickening of the arterioles, before these had had time to take place, and before this had shut off the blood from the capillaries. In any case, he made no pretension to finality in this respect, and he remained prepared to modify his views as new facts were discovered. He adhered to his view that the capillaries were the primary seat of the obstruction, whatever might subsequently take place in the arterioles. There was more in the cardio-vascular changes of renal disease than the "stop-cock" theory would account for. He added that the arterioles were thickened, not only by muscular hypertrophy, but by fibroid thickening. He was aware that Dr. Johnson maintained that the appearance of fibroid thickening was a delusive appearance due to the action of the reagents; but to that statement he demurred, for he had made a large number of experiments with various reagents, and he had convinced himself that the fibroid thickening was as real as the muscular. He thought, too, that the continued high tension throughout the arterial system would account for both kinds of thickening. Last December Dr. Johnson had written to THE LANCET in reference to his (Dr. Dickinson's) Harveian lecture, attributing renal dropsy entirely to osmosis, but now he seemed to have modified that view in favour of some active vital secreting power on the part of the capillaries. In spite of what had fallen from Dr. Powell, he inclined to the view that osmosis as a cause of dropsy was dead, irrevocably and thoroughly dead. He showed photographs of the healthy heart and of the heart in these cases, and asked them to look on this picture and then on that. He thought that Dr. Pye-Smith's suggestion as to the inflammatory nature of the œdema of acute nephritis was disproved by the analysis of the fluids in the two cases. Inflammatory fluids usually coagulated spontaneously, which dropsical fluids did not; moreover, they contained 6 per cent. of albumen, whereas the other only contained about 2 per cent. These differences were sufficient to prove that the two processes were not the same. As to the late renal dropsy being cardiac, and not renal, it was said that the tension often continued high after the dropsy had disappeared; but he did not think this was of common occurrence. He thought the rule was for the dropsy to disappear and the patient to get better as the blood pressure fell. What was more remarkable was that the dropsy went on in spite of a further increase of the tension. Of this he suggested three explanations: One was an increase in the excretion of urine; an increase in the suction action of the hypertrophied left ventricle; and, lastly, the contraction of the arterioles keeping the blood out of the tissues. He had only mentioned chlorotic anæmia, so to speak, accidentally. He had usually found high tension in that association. He never intended to convey that transudation under pressure was the only explanation. Dr. Sansom had very properly insisted upon the effects of prolonged high pressure; and of the effect of uric acid in bringing about contraction of the arterioles there could be no doubt, though he was not prepared to attach as much importance to that factor as Dr. Haig did. An excess of uric acid was unquestionably present in many of these cases, and in one instance he had found a lump of uric acid in the brain of a patient. In conclusion, he thanked the Society for the indulgence with which they had listened to his paper, and for the valuable criticisms and observations which they had made.

OPHTHALMOLOGICAL SOCIETY OF LONDON.

AN ordinary meeting of this Society was held on Thursday, May 5th, Henry Power, F.R.C.S., President, in the chair.

Mr. E. C. KINGDON (Nottingham) read a paper on a Rare Fatal Disease of Infancy, with Symmetrical Changes at the Maculæ Luteæ. The patient, aged eight months, was born at the full term, and appeared healthy until three months old; then gradually increasing weakness of the muscles of the trunk and limbs set in, so that when seen he was unable to sit up or turn over in bed. The muscles felt flabby, but the body was well nourished. The child was

Digitized by Google

apathetic, rarely cried, and the expression of the face suggested mental enfeeblement. There was no sign of disease in the thorax or abdomen; no history of any previous illness, nor of rickets or syphilis. The father and mother were not related, and were healthy people with good family histories. Their first child had died when two years of age with similar symptoms. At the yellow-spot region in each eye, covering a space nearly twice the size of the optic papilla, there was seen a whitish-grey patch, somewhat oval in shape (the axis being horizontal), with softened edges; a few retinal vessels coursed over its periphery. In the centre of the patch the fovea centralis appeared as a dark cherry-red spot. In addition there was commencing optic atrophy. The changes in the two eyes were identical. The child remained under constant observation for four months, when it died somewhat suddenly. During that time its general condition had not altered. The appearances at the maculæ luteæ persisted unchanged, but the optic atrophy had increased. Microscopic examination of the brain after death revealed marked changes in the pyramidal cells of the cortex; they were altered in shape, being mostly round or oval. The cell protoplasm was vacuolated, and formed an irregular shrunken mass around the nucleus. Sections of the spinal cord revealed "descending degeneration."

Mr. WARREN TAY communicated another case of Symmetrical Changes in the Yellow Spot Region in an Infant, closely resembling those of embolism of the central retinal artery. There were symmetrical changes in the yellow spots, exactly resembling those figured and referred to, and closely simulating those due to embolism of the retinal artery; there was, however, no obvious change in the discs. There were six children in the family, two of whom had been delicate, one of them, aged six, dying of diphtheria. The others appeared well. The parents were first cousins.

Mr. CHARLES HIGGENS made a communication on a case of Spontaneous Cure of Cataract. The patient, aged fifty-seven, consulted the author in February as to the condition of his eye. He had seen the late Mr. G. Critchett ten years before, and was told by him that he had a ripe cataract in that eye, and, as his left eye was unaffected, Mr. Critchett advised him to have nothing done. Examination of the eye detected no sign of wound on the cornea, and showed the pupil to be circular and freely movable, a good deal of opaque membrane and possibly some lens matter occupying its area; the optic disc was visible, and vision was $\frac{6}{18}$ with a + 3½ inch lens, and Jaeger 10 at 6 inches with a + 2¾ inch lens, the whole, or nearly the whole, of the lens having undergone absorption.—Mr. LANG mentioned the case of a man under his care at Moorfields Hospital, in whom a senile cataract had almost disappeared during the course of two years. The nucleus of the lens had sunk to the lower part of the capsule, and had left a central, nearly clear space. With correcting glasses the man had good vision.

Mr. HOLMES SPICER read a paper on Vasculitis in Hereditary Syphilis and the condition of the Retinal Vessels in the Retinitis of Congenital Syphilis. The ophthalmoscopic appearances showed faint white lines on each side of the vessels, beginning at or near the optic disc, and gradually increasing in thickness towards the periphery; arteries and veins were both affected, but in the slighter cases the veins showed it most. In very acute cases the vessels were entirely obliterated and converted into white threads. This change was combined with a diffuse retinitis, and with a superficial disturbance of the choroid. The microscopic appearance of the vessels showed that the intima was very greatly thickened in all the vessels; there was also an increase in the thickness of the outer coat; all the elements of which the vessel wall was made up were in places dissociated from one another.—Mr. LAWFORD inquired if there had been any opportunity of examining the vessels of other parts of the body.

Mr. SYDNEY STEPHENSON exhibited cases and read a description of the Scarring of the Conjunctiva from Ophthalmia Neonatorum. He had met with these conditions in eighty-two out of 15,316 school children examined, the percentage being much higher among pauper school children than among those of higher social grade. This scarring might be the only evidence of ophthalmia neonatorum, or might be accompanied by other results of this disease, such as corneal nebulæ, pyramidal cataract, &c.

Reviews and Notices of Books.

Atlas of Clinical Medicine. By BYROM BRAMWELL, M.D. Vol. I., Parts II. and III. Edinburgh: T. & A. Constable. 1891.

THE second and third parts of Dr. Byrom Bramwell's "Atlas of Clinical Medicine" fully justify the cordial welcome extended to the first instalment and the high hopes it elicited. The first part was so excellent that fears might have been entertained about the difficulty of maintaining such a high standard of work; these fears were, however, largely dispelled by the receipt of advance copies of many plates intended for later use, and the letterpress now supplied finally disposes of any uneasiness. The second part is mainly devoted to Addison's disease and Hodgkin's disease. The former is of course prefaced by an extract from the Sydenham Society's collection of Addison's works, to indicate the amount of credit due to his sagacity in detecting the relation between the well-marked constitutional symptoms of the affection, the peculiar pigmentation of the skin, and the structural changes in the suprarenal capsules. After this act of homage Dr. Bramwell enters at once into the symptomatology and into an analysis of the symptoms, and he enriches his description by numerous references both to cases and to the literature of the subject.

Of the pathology of this interesting disease there is a great deal to be said; but the most important section is that devoted to the observations of Drs. Alezais and Arnaud, who have shown that true sympathetic nervous ganglia are situated in the surface, and sometimes actually in the substance of the fibrous covering of the suprarenal bodies, and who think that the essential cause of the pigmentation and other characteristic symptoms lies in implication of these pericapsular nervous ganglia by a tubercular process extending from the suprarenal bodies. The various theories which have been advanced to explain the pathology of the disease are discussed with great fairness. Dr. Bramwell's opinion is that, in the ordinary typical cases, the capsular lesion is primary, and that the alterations in the nervous structures are secondary. Notes are given of two cases resembling Addison's disease, both marked by deep pigmentation; in the first the symptoms were due to Bright's disease and pregnancy, in the second they were apparently the result of chronic scurvy.

Dr. Bramwell follows with an account of some cases of diffuse melanotic sarcoma, with pigmentation of the skin, noting the rarity of this condition, but indicating the clinical features by which it may be distinguished from Addison's disease. Then comes a full description of Hodgkin's disease, or "lymphadenoma," which is illustrated by photo-gravures and sketches. Hodgkin's descriptive summary, written in 1832, is reproduced, and the independent work of Dr. Wilks in 1885 receives due notice. Throughout this section the author very properly insists upon the difficulty of differentiating cases of Hodgkin's disease from other conditions associated with enlargement of lymphatic glands, more particularly from simple local non-malignant lymphoma, and hence speaks of the prognosis with due reservation.

The third part deals with progressive unilateral atrophy of the face, chronic progressive bulbar paralysis, ophthalmoplegia, molluscum fibrosum, and xeroderma pigmentosum, and no less than twelve plates are furnished illustrating these different conditions. The pathology of facial hemiatrophy is discussed with great lucidity. The author's view is that the atrophy is the result of a nerve lesion involving the trophic nerve fibres or cells of the fifth nerve, and he considers that the balance of evidence is in favour of the central origin of the lesion. The description of chron

Digitized by Google

progressive bulbar paralysis is very graphic and very complete. Although much space is devoted to the symptomatology, practitioners will find numerous most valuable hints upon the differential diagnosis, and much that is interesting in quotations from the writings of Duchenne, Trousseau, and others. The difficult subject of ophthalmoplegia is dealt with at some length and with characteristic care and thoroughness, while the remaining subjects are passed over more briefly but very satisfactorily.

It remains to add that the plates supplied with these two parts, more particularly the coloured plates, fully maintain the high standard of excellence reached in the first instalment. They are thoroughly well executed, and indicate the leading characteristics clearly and without exaggeration. Dr. Byrom Bramwell is to be heartily congratulated upon his work, and it is to be hoped that no unforeseen circumstances will interfere with its successful completion.

Diseases of the Throat, Nose, and Ear: a Clinical Manual for Students and Practitioners. By P. MCBRIDE, M.D., F.R.C.P. Edin. Edinburgh and London: Young J. Pentland. 1892.

DR. MCBRIDE'S views on many points connected with the subjects embraced in the title of this book are so well known and valued for the authoritativeness with which they are expressed that all will welcome a text-book from his pen. We expected something above the meagre average of similar productions, and we are not disappointed. While every attempt is made to place before the student current views, Dr. McBride has generally given fully his own opinions wherever desirable. Only too often in text-books the practitioner is perplexed by numerous statements of this, that, or the other authority, and finds little to guide him in his difficulties; while what he is actually needing—viz, the author's own ideas—is only too modestly withheld. In the book under discussion Dr. McBride states his own position with regard to many controversial points, and in such cases, in all probability, his statements will prove of considerable value to the practitioner seeking definite information. In reference to these points we may quote the chapter on the General Semeiology of Nasal Diseases, or the section on the Connexion between Diseases of the Throat and Nose and Middle Ear Affections. Dr. McBride appears to think that active and operative treatment of these regions is far too often undertaken as a matter of routine; while he impresses upon the reader the theory that affections of the anterior nares and pharynx, when coexisting with middle ear disease, need only be treated in so far as they are producing direct symptoms. In the main we are inclined to endorse this view, though, we suspect, it may be carried too far. Anyhow, a book that condemns the ruthless and irresponsible operating that is at present too much the fashion is a most desirable addition to our literature. There is little fault to be found. We could wish that in certain cases the author had been a little more communicative as to practical treatment; we do not think that everything has been said in some cases. Thus in the chapter on Chronic Laryngitis no allusion is made to the association of the affection with nasal obstruction, and its cure by the rectification of the latter condition. We think that although Dr. McBride may not agree with such views he yet should have made some reference to them, as they are endorsed by many trustworthy laryngologists. Indeed, he even advocates the use of a respirator, which can only be occasionally necessary when the nose is unable to do its work. Still more striking than this omission is the disregard of rhinitis sicca in the production of laryngitis sicca. This we should have opined was beyond all question. To be perfectly candid, although we have spoken strongly on the commendable attitude taken by the author in reference to the absurdities circulating with regard to the importance of a theoretical perfection in the condition of the nasal passages, we are yet inclined to think that he has gone too far in the opposite direction, and that the portion of the work devoted to diseases of the nose is somewhat meagre. Laryngeal and pharyngeal affections are fully discussed, but we are of opinion that the best portion is that devoted to the ear. Some will be a little doubtful as to the wisdom of incorporating this with the other sections, though doubtless there are arguments in favour of such an arrangement.

That Dr. McBride has plenty of material wherewith to fill a good volume is at once made evident by the paucity of illustrations. He has thought it inadvisable to crowd the pages with engravings of instruments, and we suspect that many a general practitioner will find this a somewhat serious omission. An illustration will convey a better idea of an instrument, and in smaller space, than could be given in the letterpress. All the illustrations are chromolithographs, incorporated with the text. Those representing diseases of the larynx are all that could be desired; while those, on the other hand, illustrating nasal affections are as conspicuously unsatisfactory. Thus we find an illustration of a mucous polypus as seen *in situ*, the tumour being a bright prussian blue, and its surroundings undistinguishable. The representation of the normal appearances of the nasal structures as seen from behind is incorrect in drawing and colour, and would prove very misleading to a beginner. But the illustrations of pathological conditions in the tympanic membranes are not surpassed in excellence in any of the many admirable atlases extant.

The general appearance of the work reflects great credit upon the care of the printers and the liberality of the publisher. The paper and typography could not be better; and although these are very small matters in discussing the value of a work, yet accuracy and elegance generally prove as attractive to the reader as they doubtless are to the author. We hope to see many editions of this valuable book.

A Manual of the Diseases of the Nervous System. By W. R. GOWERS, M.D., F.R.C.P., F.R.S. Second Edition. Vol. I.: Diseases of the Nerves and Spinal Cord. London: J. & A. Churchill. 1892.

EVERYONE who is interested in the subject of nervous diseases must welcome the new edition of a work which is already a classic in more than one language and certainly on two continents. Dr. Gowers is to be congratulated on the partial completion of his arduous and self-imposed task, and upon the manner in which he has brought the discussion of the various subjects up to date in this new edition. It is in every way a worthy sequel to its predecessor, and in its thoroughness and completeness is almost beyond criticism; and if we call attention to a few points which have struck us in a perusal of the book, it is only because they have seemed to us points requiring special treatment.

A substantial addition of 150 pages has been made to the book. Of these, fifty are devoted to a detailed and very complete account of multiple neuritis. The account, as we have said, is complete, but it has the greater advantage of being extremely suggestive. Yet it seems to us that the classification into varieties has been carried to an extreme, although it may be that such a classification, in the elucidation of a subject to which only recently attention has been directed, is not only useful, but necessary, and may be regarded as the framework, to be replaced in good time by the complete and solid structure. Besides this section there are several other new ones, the most important of which are probably those on the peroneal type of atrophy and on Morvan's disease. In connexion with the latter also may be mentioned the exceedingly clear and succinct account given of Syringomyelia, a clinical entity only re-

cently recognised, and the pathological condition underlying which probably varies in different cases. The chapter also on Muscular Dystrophy strikes us as wanting in that firm cohesion which characterises most of the work. Here, too, there is a tendency to multiply types when we have really reached a stage at which the essential unity of various conditions is becoming more and more evident.

It would be idle to particularise the various parts to which additions have been made. They occur on almost every page, and the alterations are nearly always improvements. We have sufficiently indicated the excellences of the work, and we can give it no higher praise when we say that it is in every way worthy of its predecessor and of the reputation of its author.

Analytical Records.

LAKOLA PREPARATIONS.

(LAKOLA LIMITED, ST. ANDREW'S BRIDGE, GLASGOW.)

THE basis of the preparations we have received from this firm is the kola nut, and accordingly they all contain caffeine. The alkaloid was readily extracted on boiling a portion of the samples with chloroform after making them into a paste with lime. Caffeine so obtained was recognised by its silky crystalline appearance and by the red colour produced on evaporating it to dryness with chlorate of potash and hydrochloric acid; the red colour was changed to purple on addition of ammonia. Lakola essence is a spirituous extract and has a nutty flavour. It is a useful form of restorative, which may be taken in aerated water, in milk, or in tea. Lakola powder is similar to cocoa in appearance and taste, and is intended to be used in the same way. "Lakola" itself is a pasty mass, which is directed to be eaten spread upon bread in the same manner as butter, or to make cocoa, while the enhanced value of lakola chocolate is attributed to the fact that, in addition to ordinary chocolate, it contains the important constituents of the kola nut. Where, therefore, the restorative and sustaining properties of the kola nut are of value these preparations may confidently be tried.

BROWN BREAD.

(J. T. O'CALLAGHAN, WOOD GREEN, N.)

The meal from which this bread is prepared is said to be made by the roller process—that is, it is ground finely enough to pass through an 18 in. mesh wire sieve, so that it is freed from large flakes of bran and objectionable chaff. While it contains also the whole of the wheat grain, the external fibre and the beard are removed by decortication. Branny particles were recognised under the microscope, but they were evidently very small. There is doubtless a higher proportion of nourishing constituents in whole wheat meal, but it should of course be ground finely, as otherwise the branny particles may prove irritating. The bread under notice appears to have been prepared from meal thus scientifically treated.

MELLIN'S FOOD BISCUITS.

(G. MELLIN, MARLBRO' WORKS, PECKHAM.)

These biscuits are stated to contain about 50 per cent. of Mellin's food. This statement is to an extent confirmed by the fact that the mineral matter, amounting to as much as 2·02 per cent., consisted largely of alkaline phosphate. They are doubtless a valuable and convenient form of food, but their flavouring of ginger will not appeal to everybody's taste.

CAFFYN'S JELLY CARNIS.

(THE LIQUOR CARNIS CO., LIMITED, 50, HOLBORN-VIADUCT, E.C.)

It is satisfactory to find that the claims made with regard to this preparation are fully justified according to the results of independent chemical examination. First, the spectroscope showed that it contained the hæmoglobin of meat unaltered, as on dissolving some of the jelly in cold water, and placing the solution in a glass tank in front of the spectroscope, two well-defined absorption bands characteristic of fresh blood were very distinct. Then on boiling the solution a coagulum was obtained, and the filtered liquid no longer exhibited the absorption spectrum. One fluid ounce of the jelly so treated yielded no less than 10·19 grains of solid albuminous principles. Further examination gave the following results:—Moisture, 46·50 per cent.; organic matter, 47·91 per cent.; mineral matter, 5·59 per cent., consisting chiefly of soluble phosphate. The jelly possesses a sweet, pleasant taste, is attractive in appearance, and, on account of the presence of a small quantity of harmless preservative, keeps well. We regard it as a valuable addition to the excellent nutrient preparations already made by this company.

STERILISED MILK.

(COMPAGNIE GÉNÉRALE DES LAITS PURS, PARIS. F. TURIAN, 32, OAKFIELD-ROAD, STROUD-GREEN, N.)

The method adopted to sterilise this product may be pronounced to be a distinct success, inasmuch as our analysis shows that the composition of the milk is not altered by the process, all the valuable food elements being therefore retained. Moreover, the samples, after standing in a warm corner of the laboratory for several weeks, were found at the end of that time to be perfectly sweet. The results of analysis were as follows:—Total solids, 12·70 per cent.; non-fats, 9·38 per cent.; fat, 3·32 per cent.; mineral matter, 0·70. The fat was in a separated condition. The sterilised milk resembled boiled milk in taste. Search was made for preservatives, but without success.

TAKARADZUKA MINERAL WATER, JAPAN.

(H. J. STOCKTON, 16, PHILPOT-LANE, E.C.)

A peculiar acidulous flavour distinguishes this water from the rest of its class. It is agreeably sparkling, contains no organic matter, and yields on evaporation fifty-six grains per gallon of saline substances containing a notable quantity of iron and salicylic acid along with common salt and the carbonates of lime and magnesia. There exist, we understand, two distinct qualities of this interesting water, one intended for medicinal use and the other for the table. We presume that the sample of water containing the amount of mineral constituents above indicated is intended to be used medicinally, as according to the published account of an analysis before us the water examined contained only 35·63 parts of saline matter in 100,000, or 24·94 grains per gallon; that is, rather less than a half of the quantity found by us in the above specimen.

SPANISH WINES.

(A. SORDO LOPEZ, 15, GEORGE-STREET, PORTMAN-SQUARE, W.)

The two samples of wine submitted to us possess characters of their own which are probably distinctive of the wines produced in the district of Valdepenas in the south of Madrid. Red Valdepenas is the name of a full vigorous claret resembling good Burgundy. It is remarkably free from acid, has a delicate bouquet, and contains a distinct quantity of iron. White Valdepenas is more like a light dry sherry with a peculiar and almost smoky flavour. Both are really excellent wines, and they are offered at a very moderate price. Red Valdepenas submitted to analysis gave the following data:—Alcohol, 12·30 per cent. by weight (equal to 15·20 per cent. by volume); extract, 2·6 per cent.; mineral matter, 0·24 per cent. The white wine gave the following results:—Alcohol, 10·95 per cent. by weight (13·55 per cent. by volume); extract, 1·43 per cent.; mineral matter, 0·32 per cent.

UPPA COCOA (VAN HAEFTEN'S).

(VAN HAEFTEN, HOLLAND.)

As should be the case with all genuine cocoas, this specimen yields an infusion of good flavour, is easily soluble, and contains no excess of indigestible fat.

THE LANCET.

LONDON: SATURDAY, MAY 14, 1892.

THE interim report of the Royal Commission on Vaccination, the text of which we print elsewhere, is a document of considerable importance. And its importance is increased when we remember that in order to give present effect to the principal recommendation embodied in the report, legislation dealing with the question of vaccination will become necessary, and this before the Commission have so much as heard some of the principal witnesses on whose evidence such a recommendation should be based. One of the headings under which the Commission decided to take evidence is—"Any improvements that can be suggested in the present law or its administration for the purpose of removing objections to vaccination or making it more effective." The Commission have been sitting nearly three years, but they have not as yet even reached this heading, and although they have before them volumes of evidence as to "the case in favour of vaccination," and as to "the case against vaccination," they say not a word on these important subjects, but, oddly enough, elect to criticise the "administration" of "the present law," the evidence as to which is not yet before them. This attitude is, to say the least, a curious one; and considering that every "interim" report is supposed to be subject to revision when the full report follows, it seems difficult to understand how legislative effect can be given to their recommendation, and if no such effect is intended to be given, the result of the report can only be to leave matters in even greater confusion than they were before; for vaccination authorities and magistrates will, on the one hand, have a statutory duty to perform, and, on the other hand, they will have been told that the performance of that duty should in one respect "no longer be possible."

We have no intention of entering into the question of the prison treatment of those who break the law as to vaccination and whose fines are not paid. We have much sympathy with these people, whom we believe to be largely guided by persons who lead their followers into an attitude of unbelief which the leaders do not themselves entertain, and who, for reasons which we do not propose here to discuss, contrive to keep dark their true convictions as to the protective power of vaccination against small-pox, by involving the question in a number of side considerations. The real importance of the interim report lies in the statement that "the imposition of repeated penalties in respect of the vaccination of the same child should no longer be possible." It would be idle to say that a recommendation bearing on this subject was not expected to appear when the Commission had ended its labours, but there are not many who were prepared for such an unconditional abandonment of this power of enforcing obedience to the vaccination laws, nor will there be many who are able to appreciate the main reason assigned by the Commission for the change

The Committee of the House of Commons, which was appointed in 1871 to inquire into the operation of the Act of 1867, reported that, "with regard to repeated convictions and penalties," they were of opinion that "whenever in any case two penalties or one full penalty have been imposed upon a parent the magistrate should not impose any further penalty in respect of the same child." A Bill embodying the suggestions of the Committee was passed by the House of Commons, but the clause giving effect to this recommendation was struck out by the House of Lords. The present Commission go much further, and they suggest that, quite irrespectively of the amount or the number of fines, repeated penalties ought not to be possible; and if legislative effect be given to this there will be districts in which the only alternative will lie between the protection of children against small-pox or the payment of a fine of sixpence or a shilling. And what is the main reason assigned for this? Even those, say the Commissioners, who incline to the view that vaccination ought to be compulsory "believe that any advantage which may arise from the tendency of repeated convictions to increase the number of the vaccinated is more than counterbalanced by the resentment and active opposition which they engender." As we have already implied, the recommendations of a Royal Commission should be based on the evidence laid before them, and at the onset of the sittings of the Commission in question it was clearly the intention that this should be so in the present instance, for whilst "objections" were to be heard, "the reply to these objections' was to follow. Doubtless objections to repeated penalties have been heard, but those who administer the vaccination laws—namely, guardians and their representatives and magistrates—have not been heard, and the matter has thus been decided on lines quite foreign to those usually governing judicial decisions in this country. This is the more unfortunate because we are convinced that if the Commission had only waited until they had heard "the reply" they would have received from those guardians who have honestly done their duty to maintain the law abundant evidence to show that the reason assigned is contrary to experience. One single small fine has but little deterrent effect; the trouble of paying it is trivial to a parent who thinks less of protection against small-pox than of a few days and nights passed with an infant rendered irritable by reason of the progress of vaccinia; and whereas many careless people—and it is essentially the poor and ignorant who are careless as to this—are willing to incur the domestic difficulties involved in vaccination rather than pay a substantial fine or be subject to repeated legal proceedings, many will be found who, having no knowledge or even opinion concerning the protective power of vaccination, will elect to pay a fine in districts where the magistrates are lenient, and so go scot-free, until small-pox comes, when they will flood the vaccination stations which they formerly affected to despise. In this way it is that the many who are careless, not the few who are real opponents to vaccination, will swell the number of the unvaccinated. And this it is that the Select Committee of 1871 evidently had in view when, on the evidence laid before them, they decided that either a full penalty or two penalties must in each case be imposed before interference ceased.

Digitized by Google

We must now await the result of the issue of this ill-timed document, trusting that evidence will still be forthcoming to show the Commission that they have gone beyond the necessities of the case, even as that case is put forward by themselves; and remembering that the Commission distinctly announce that they have arrived at their conclusion "quite independently of the question whether vaccination should continue to be compulsorily enforced or not." This, and the vital question as to the value of vaccination as a protection against small-pox, are points not touched upon, and they will, apparently, not be in any way dealt with until the final report is issued.

SOME little stir has been caused in the minds of our professional brethren in Ireland by an Order in Council which was lately made by His Excellency the Lord Lieutenant, and which contains the following paragraph: "When any vacancy shall happen in the office of consulting and visiting physician or of apothecary in any district asylum, no person shall henceforth be appointed to fill the same." The Council of the Irish Medical Association have taken umbrage at this ukase, in regard to which they have issued a somewhat lengthy protest, in which they urge, upon a variety of grounds, the retention of the office of visiting physician. They hold that the services of an occasional consultant are available only at about three or four out of the twenty-two asylums, and that they can never be an efficient substitute for those of the regular visiting physician. They further urge that, "from a public point of view, it is undesirable that the responsibility for the control of several hundred persons under coercive discipline and penal restraint should be vested in any one officer, however exemplary or competent." They add: "The public at large is very jealous, and even suspicious, as to the disciplinary arrangements of lunatic asylums; and the Council respectfully submits that, even if there be no reasonable ground for such jealousy or suspicion, it is very undesirable to remove from the lunacy system the only extern officer in daily communication with the inmates, and independent of, and irresponsible for, the official management of the institution."

We are not prepared to accept the expressions "coercive discipline" and "penal restraint" as conveying a truthful idea of what asylum life in Ireland either is or is intended to be, but we are not unwilling to give the views of the Council in their own words, as the fullest expression of all that can be said in favour of retaining the office. We are more than doubtful whether those words will convince the ordinary lay mind as to the need for a visiting physician; still less will they bring conviction on this point to the minds of those who have any practical experience of the working and administration of asylums for the care and treatment of the insane. Putting aside indications in the very statements themselves, the best evidence that the arguments of the Council are theoretical ones only lies in the fact that they imply that the office of visiting physician to an asylum is an unmixed good in which the public should be asked to bury all its jealous fears and its suspicions. A visiting physician has no doubt an awkward, and frequently an unenviable, part to play. If he asserts himself and makes his presence and his prescriptions felt by the inmates, he cannot but be conscious that he is upsetting the discipline of the asylum by interfering with the authority of the superintendent, and that he is doing as he would not like to be done by. If he does not assert himself and make his presence felt, and practically does nothing, he may possibly feel that he is a nonentity, and that he is more or less receiving the reward of duties which he has not duly performed. He is on the horns of a dilemma; he cannot help himself, and his most successful and least troublesome policy is one of masterly inactivity and of complacent negation—for which the public has to pay.

We are far from saying or thinking that the ideal office of visiting physician was originally a useless creation; but experience appears to have shown that the unavoidable interweaving of the duties of the visiting physician with those of the resident medical superintendent has a tendency to weaken rather than to strengthen the administration of an asylum. The history of this question puts us in possession of the fact that in countries where the office of visiting physician existed, it had sooner or later to be abandoned as incompatible with the best and most desirable results, and we are not aware of any insurmountable grounds upon which Ireland can insist upon maintaining a post whose equivalent has been expunged in England, Scotland, France, Germany, and America, countries where the treatment of the insane has admittedly made most material progress in the direction of humane and kindly consideration with most gratifying success. Indeed, so far back as 1858 a strong Royal Commission on Lunacy for Ireland recommended in effect that the office should be discontinued; and at that time the amount of extramural visitation of asylums, and of contact of the inmates with the outer world, was much more restricted than it is in the present day.

Coming to more recent times, the question has been frequently under consideration when the treatment and management of lunatics and lunatic asylums have been discussed. In 1890 a Committee on Lunacy Administration in Ireland was appointed by the Lord-Lieutenant, and it consisted of Sir ARTHUR MITCHELL, one of the Medical Commissioners in Lunacy for Scotland; Mr. HOLMES, Treasury Remembrancer for Ireland; and Mr. MACCABE, Medical Commissioner for the Local Government Board for Ireland. In their report they speak as follows on this subject: "Consulting and visiting physicians are attached to all the district asylums of Ireland. We are of opinion that a new Lunacy Law should contain provisions for bringing this arrangement to an end, either by enacting that vacancies, as they occur, shall not be filled, or in some other way. Visiting physicians relieve superintendents of responsibilities of which they should not be relieved. At the same time they do not afford him the assistance which consultants afford to general practitioners, who in their difficulties take the advice of a surgeon in certain cases, of an oculist in others, of a physician in others, of an obstetrician in others, and so on. A superintendent should be allowed, when he is in difficulty, to obtain the advice which is likely to be useful to his patient, in view of the nature of the malady in connexion with which the difficulty arises. He may be safely trusted to do this judiciously.'

Digitized by Google

This is surely not unreasonable, that the insane in asylums should have the same opportunity of being specially treated as the sane outside. On this report, and in taking a general and comparative view of all the circumstances, practical and theoretical, with which the question is invested, we feel satisfied that his Excellency and the Irish executive have been well advised in abolishing the office of visiting physicians as vacancies occur. At all events, there are not wanting ample grounds upon which the experiment may be tried, and even if it should result in failure the office can be reconstituted.

THE important duty of getting rid of uninhabitable houses or insanitary property devolves on the sanitary authority, and requires to be carried out with discrimination. In towns of less than 100,000 the corporations, as a rule, are loth to undertake on their own account any buildings for the population so displaced; and, on the other hand, private enterprise in the way of building houses for such tenants may fall short of actual requirements. The occupants of these insanitary houses are of the lowest and poorest class, of whom house-owners and agents generally fight shy. There will always be a residuum in the population of a town. In large towns and cities where CROSS'S and TORRENS' Acts can be adopted the difficulties are not so great, and the ratepayers not so punctilious as to the spending of their money as is the case in small towns. In small towns every penny spent on sanitary measures is watched with a jealous eye; and as it is difficult to show a money return for any improvement, it is not easy to persuade the inhabitants that the health of the people is a matter of primary importance and one that well repays any outlay. As an example of the slowness of reforms in the destruction of unhealthy dwellings we may instance Wigan in Lancashire, an old town with many dilapidated dwellings, and a population of over 55,000. The Insanitary Houses Committee, in consequence of charges being made against them of proceeding with undue haste in demolishing houses unfit for human habitation, have just issued a report of their doings. They state that on Jan. 18th, 1886, their medical officer (Mr. BARNISH) called attention in his monthly report to that of Dr. BUCHANAN (the late medical officer of the Local Government Board) in 1870. Dr. BUCHANAN stated that amongst the chief sanitary defects of Wigan were the badly constructed and badly ventilated houses, and the courts with back-to-back houses. Mr. RADCLIFFE confirmed this report in 1873.

Mr. BARNISH in this report condemned twenty-two houses under the Artisans and Labourers' Dwellings Act, 1868, the borough surveyor confirming this decision. On April 12th, 1886, the town clerk presented a report on the law, together with information received from various towns, as to the action they had taken with respect to insanitary property. The sanitary committee then decided to take no action till the medical officer had reported on the whole of the insanitary houses in the borough. Dr. PAGE on Nov. 15th, 1886, urged that the authority should act upon the reports of the medical officer of health and the borough engineer. In January, 1887, the medical officer presented the first section of his report dealing with the whole of Scholes Ward, in which he condemned 1120 houses. The borough engineer stated that of these 754 houses could not be rendered sanitary by means of structural alteration. On Aug. 3rd a special committee was appointed to consider the question of dealing with insanitary property and to report to the Council thereon. The committee found that this property in many cases belonged to people depending upon the rents for a bare subsistence, and, as the Council had no power to compensate, the committee, on Oct. 1st, 1887, decided to recommend the Council to apply for power to pay compensation for property demolished, and for this purpose to borrow £10,000. This recommendation was adopted on Oct. 29th, 1887. The Council in 1889 accordingly promoted a Bill in Parliament (The Wigan Corporation Act, 1889), which was passed, and Section 98 gives the Corporation power to pay compensation for buildings unfit for habitation.

On Nov. 22nd, 1889, the Insanitary Houses Committee was appointed, and in May, 1890, they decided to proceed under the Artisans and Labourers' Dwellings Acts. After the passing of the Housing of the Working Classes Act, 1890, which repealed the Artisans and Labourers' Dwellings Acts, the Council adopted its provisions, and subsequently proceedings were taken against various owners of insanitary property, the result being that in the majority of cases the owners agreed to demolition on receiving compensation at the rate of five years' purchase on an average of three years' net rental, whilst others have made structural alterations so as to render the property habitable. The number of houses with regard to which proceedings for closing have been taken since 1890 is 484. The number of those actually demolished, and for which compensation has been paid, is 199; of those not compensated for, but demolished, 72; of those which owners have agreed to demolish, 84; of notices served and action pending, 101; and of premises made sanitary, 28. Fifty-nine out of the 484 houses were unoccupied for twelve months before demolition. The total amount paid in compensation was £3430 8*s.* 10*d.* Since the first block of insanitary property was demolished building plans have been passed for 570 houses of the cottage class, the number erected and occupied being 235. The number of houses in course of erection is 144. We cannot say that there has been undue haste in dealing with the worst class of cottage property; however, the matter has been taken in hand, and it will now be the duty of the Sanitary Committee to prevent overcrowding in the new dwellings.

Wigan may be fairly congratulated on having made some progress since Sir G. BUCHANAN visited the town in 1870. Since then the privy system has been abolished, and the pail system adopted; a complete system of sewerage, with a modern sewage farm, has been made at great cost; a sanatorium for infectious diseases on the most modern and approved plans has been provided; and now what with the destruction of unhealthy dwellings, the erection of new baths, and a good water-supply, the town may claim to be on a par with any other town of a similar size.

IT had been expected by most of the graduates of the University of London that either at the meeting of Convocation on Tuesday last, or at the Presentation on

Digitized by Google

Wednesday, some definite course of procedure on the part of the authorities of the University, in view of the recently appointed Royal Commission, would have been decided on; but any such anticipations were disappointed. Both meetings have passed, and all we learn is that the Senate will not take up any attitude of simple obstruction during the proceedings of the Royal Commission, and that the Senate will steadily persist in their endeavour to keep up the present high standard of the degrees, as otherwise their prestige might be diminished. Lord DERBY, who presided on Presentation Day for the first time as Chancellor, was anything but optimistic in his survey of the position of the problem of higher education in London, and expressed a great doubt whether the Royal Commissioners would come to a unanimous conclusion. He also, as has been the usual course throughout the agitation, ignored the subject of medical degrees, and their vital interest to the public, to London medical teachers, and to students. The importance of this question to the student—namely, whether he can obtain a degree by studying in the best clinical schools in the kingdom on similar terms to those on which it is granted by Scotch and provincial universities having inferior facilities for practical teaching—seems to have been passed over by a Senate which has no other idea in medical education than to fix an abnormally high standard for a pass degree and then shut its eyes to the disadvantages which this entails on an average London medical student. According to Sir JOHN LUBBOCK there is no need for a second University in London, but should a Teaching University ever be established, the proper place, he considers, for the existing University is at its head. We would point out to Sir J. LUBBOCK that the present University performs no university functions, has no special relations to higher education in London, or to the colleges and medical schools in which such an education is given, and that all attempts at its remodelling in this direction have proved unsuccessful. Must we believe that such an advocate of scientific education fails to see that an examination board for the British Empire and a local Teaching University for this metropolis are essentially different in design and in functions?

At the meeting of Convocation it was resolved to request the Annual Committee to "represent and guard the interests of Convocation generally in all matters connected with the Royal Commission, and any scheme which may be submitted to it," and the House was very excited on being told that no member whom they could regard as a representative of the London University had been placed on the Royal Commission. Mr. ANSTIE, Q.C., who is a member of Convocation as well as of the Senate, was at once stated to be only the nominee of the latter body. Evidently Convocation does not agree with the Chancellor as to the scrupulous fairness with which all the bodies interested are represented on the Commission. The opinions of a large number of London graduates, and the spirit in which they may be expected to approach a question which is vital to the metropolis, may be best judged from the two propositions laid down in a circular issued to influence the election of members of the Annual Committee, and which states: "(1) That no second University should be established in London; (2) that the University should be extended so as to fulfil any reasonable requirements of the Royal Commission in respect of a Teaching University, but without any lowering of the present standard of degrees, and so that students unattached to any institution associated with the University should not be placed at a disadvantage." Here we have it plainly laid down that Convocation is to do everything in its power to prevent any lowering of a degree—which has been declared to be an Honours degree—to a pass standard, and to oppose the formation of a real Teaching University, which would not be tied by the traditions and prejudices of the existing University. It is clear that, if the Senate is not prepared to adopt a policy of obstruction, a large number of the graduates will do all they can to prevent the London students obtaining the just advantages which are granted to those who have had a similar education elsewhere. If the conclusions of the new Commission—over which Earl COWPER, who is now returning from Spain, will preside— in any way correspond to those of the former Commission and of the Privy Council, it will be the duty of Parliament to prevent such an obstructive attitude being again successful.

Annotations.

"Ne quid nimis."

PRESENTATION TO SIR GEORGE BUCHANAN, M.D., F.R.S.

WE drew attention a short time since to the proposal to present to Sir George Buchanan, F.R.S., some substantial and permanent memento of the esteem and regard in which he is held, and of the illustrious services which he has rendered to medicine as a science, and especially to preventive medicine, during the long term of his official career in the Public Health Department of the State, both under the Privy Council Office and the Local Government Board. We are now able to announce that an important general committee has been formed with a view of giving effect to the proposal, and that quite apart from this committee the scheme is receiving the active support of a number of leading members of the medical profession and of the Public Health Service. It is also noteworthy that the Society of Medical Officers of Health have expressed a desire that, independently of representation on the general committee, their hearty coöperation in the proposal should be prominently set out before the public and the profession. The amount of subscription is limited to a maximum of two guineas, more importance being attached to securing a large number of subscribers than to the total amount of the subscriptions.

THERAPEUTICS IN PARLIAMENT.

WHATEVER may be thought of Parliament, it is not a body from which one expects much light in questions of medical education, especially at 2 o'clock in the morning. This was the hour at which Mr. Balfour, with a humanity which cannot be too much admired, restrained himself when invited by Dr. Clark to speak on the motion for presenting an address to Her Majesty praying her to withhold her consent from certain Ordinances made by the Commissioners under the Universities (Scotland) Act, 1889. We are not disposed to blame either members or the Government for refusing to interfere with the ordinances, especially in an exhausted House, at the end of another discussion on an excited subject. For all that, we heartily approve the protest entered by Dr. Farquharson, in the name of teachers

Digitized by Google

of materia medica and therapeutics, against what must be regarded as a thoroughly retrograde step in the recent ordinances which place the examination in these important subjects at the time of the examination in anatomy and physiology. It is just twenty-one years since the following resolution was passed by the General Medical Council on the rightful place of these subjects:—"That it is desirable that the instruction in pharmacy should be separated from that in therapeutics, and that the former should be obtained at an early and the latter at a later period of the professional curriculum." This subject was much discussed at that time. The resolution expressed the view of all the best authorities on medical education of the time, and it was proposed and seconded by the very two members of the Council who carried most weight on such questions—namely, Dr. Parkes and Sir Robert Christison. Ever since then the subject of therapeutics has been placed at an advanced stage of medical education, and the examination in it has been correspondingly late. It is, indeed, obviously absurd that a student should be examined in the action of medicines and their uses in disease before he has been tested in physiology and had the means of learning the nature of disease, the extent to which its course can be affected by drugs, and the wisdom of attempting any such interference. This, in fact, is one of the latest lessons to be learnt by the best students and by the wisest practitioners. We entirely sympathise with Dr. Farquharson and the teachers of materia medica and therapeutics in their opposition to this part of the recent ordinances. They will, of course, not abandon their opposition. They will surely be heard by the Privy Council, and it cannot be doubted that their lordships will, on such a matter, take into account the long-established recommendations of the General Medical Council. The inspectors of the Council and medical examiners are constantly finding grave ignorance of the uses and the doses of medicine even in otherwise accomplished and creditable students, and this is of the very essence of the question of qualification to practise. The Ordinances also reduce seriously the education in practical pharmacy. We cannot now discuss the best ways of improving this. But it is as reasonable to expect a soldier to do well in battle without familiarity with guns and swords as to expect a medical student to do well without a sound familiarity with the chief properties of the principal drugs and their preparations.

PROFESSOR MOSSO ON FEMALE EDUCATION.

ANTHROPOLOGICAL RESEARCH has no more acute and independent votary than the Professor of Physiology at Turin, whose lecture on "Brain Temperatures" before the Royal Society we had occasion recently to summarise and comment upon. His treatise, "Sulla Fatica"—on the physiological antecedents and pathological consequences of exhaustion, physical and mental,—is already a classic, exemplifying as it does that combination of scientific substance with literary form which, as Professor Butcher has just reminded us lately, reached its highest development in Ancient Greece. As much may be said of his scarcely less brilliant book, "Sulla Paura,"—on the phenomena of fear—a medico-psychological study which his compatriots point to with justice as a very favourable specimen of the subtler, while rigidly scientific, work of the sub-alpine school. Nor must we omit from his anthropological "record" his investigations into the craniology and general physical development of the Roman soldier—investigations which led up to the proof that the far-famed Tenth Legion—the veterans of Caius Julius, who "went everywhere and did everything"—were not superior in physique (whatever their discipline may have been) to the British, or even the continental, soldiery of the present day. These conclusions, indeed, gave direction and force to his recent paper on "Reform in Athletics," in which he points out for the benefit of his compatriots how far their gymnasial adjuncts to school work proper are deficient in the method and the *rationale* which made the Greek and Roman *palaestra* at its best an admirable "condition precedent" of the *mens sana in corpore sano*. The views of so accomplished and impartial an investigator and critic are eminently worthy of consideration, especially on a subject so keenly controverted as the medical view of "sex in education." On this theme of present interest Professor Mosso delivered on the 6th inst., in the presence of the Queen of Italy, a brilliant discourse—the last of the series on the education and the work of woman, which have been given under Royal countenance during the winter and spring at the Collegio Romano of Rome. The lecture was in all respects suitable to the occasion and creditable to its author, and we shall take an early opportunity of summarising its leading positions as the contribution of the most eminent of Italian physiologists to the *quæstio vexata* of fitting woman for her place in the household and in society.

NOTICES TO CORONERS FROM MEDICAL PRACTITIONERS.

IN THE LANCET of April 30th allusion was made to some remarks which Mr. Oliver Pemberton, the coroner for Birmingham, felt called upon to make at an inquest as to the duty incumbent upon medical practitioners of duly informing the coroner of any deaths occurring under circumstances which might render notification to the coroner necessary. We have received from Mr. Pemberton a copy of the printed form which he uses and sends to members of the profession. Coroners have complained justly of the various modes in which the information regarding unregistrable deaths reaches them. A person dies suddenly, or a body is found, and it often becomes a case of "What is everybody's business is nobody's business." Sooner or later a medical practitioner is called, and as he is generally the best informed person present, often the only one competent to do so, he should not fail to send notice to the coroner. The information which he is able to give is most valuable, and no time should be lost in sending it, either by post, by messenger, or even by telegram, should distance render this desirable. Coroners' inquests, coroners, and especially medical coroners, are very much in evidence just now, and it behoves all members of the profession to do their utmost to make inquests exhaustive medical inquiries into the cause of death.

INFANTICIDE UNLIMITED.

THE records of infanticide in this country have revealed nothing which will equal in methodical and callous wickedness the disclosures recently made in a Russian court of law. The history of a trial which has just reached its close at Vilna states that eleven persons have been charged and seven convicted of the deliberate murder, or complicity in the murder, of at least sixty-five infants. These children evidently belonged to the "unwanted" class. Many of them appear to have perished merely from wanton exposure and neglect. Others were poisoned, drowned, strangled, or otherwise suffocated. The case, almost, though as we shall see, not quite, unique in its multiplied barbarity, is in several ways deserving of particular note. The motive was obviously that of gain. Murder was adopted merely as a means of livelihood. Its plan followed no regular indications, but was covert or open, violent or subtle, as circumstances might seem to require. It is remarkable, however, that its perpetrators appear to have acted with singular want of caution, as if liable to no great risk of detection. It has been stated that they were persons of Jewish extraction, though whether this assertion

Digitized by Google

can be substantiated we are unable to say. It recalls what we have always regarded as a slander of the middle ages, and one which is utterly out of keeping with the ordinary character of the Jews—a people essentially law-abiding and particularly averse to crimes of violence. Their accusation in this case may possibly prove to be only another instance of myth created by racial prejudice. However this may be, the commission of a series of aggravated crimes with so little precaution, taken along with a like precedent reported a couple of years ago (THE LANCET Nov. 22nd, 1890), cannot but suggest a doubt as to the efficiency of executive authorities. Such would be its certain consequence in this country, and probably in Russia also. Notwithstanding the vastness of that empire, decentralisation is not a strong point in its system of government. A question naturally arises whether this principle should not be more freely applied, due regard being had to its orderly administration. By this means, aided by special provisions which would not be superfluous in the law of any country, such monstrous excesses of crime as those above described would become practically impossible.

THE FLESH OF DISEASED CATTLE.

No idea can be formed of the amount of flesh of animals which have died or been killed because of disease, that finds its way into the market as human food. There can scarcely be a doubt that thousands, perhaps tens of thousands, of cattle, sheep, and pigs are bought by the less reputable butcher or the "dropped meat salesman," and prepared by them for consumption, the beasts being at the time of purchase hopelessly ill or already dead. A great traffic must be going on in such flesh, as the carcases are rarely buried, and inquiries at the knackeries tend to prove that they very rarely find their way to these establishments. It is generally the custom for the owners of sick animals to send for the butcher to take them away either dead or alive, and probably after they have received a large quantity of drugs, some of these being, perhaps, of a poisonous description. What becomes of the carcases we can only surmise, but that they are dressed and exposed for sale can scarcely admit of a doubt; indeed, it is a moral certainty to which veterinary surgeons and others could testify. Even in the ordinary slaughter-houses diseased animals can often be seen either before or after death, and the fact of their flesh being refused sale is never heard of. The butchers could tell some startling stories with regard to this matter if they cared to do so; but everything is kept dark respecting it, and it is only at rare intervals that a chance discovery is made of some carcase that should have been buried, being found either in transit to the meat market or actually exposed for sale on the butcher's stall. The slaughter-houses are private places where anything may be done in the way of dressing up diseased carcases without much fear of detection, either there or afterwards; and there is only too much reason to apprehend that great cruelty to animals is inflicted at times in such obscure places. The only remedy appears to be the introduction of public abattoirs wherever possible, and, where these cannot be established, the institution of a system of thorough inspection of the private slaughter-houses. There should also be some means of preventing the carcases of animals that have died from disease, or been killed on the owners' premises because of illness, from finding their way into the meat market, unless certified by some competent person as fit for human consumption. For it must be remembered that in the great majority of instances such flesh must be not only of poor quality, but possibly absolutely dangerous either from its own special poisonous properties, or because of the drugs which may have been administered before death. When the carcases have once been dressed by a cunning butcher—as men who engage themselves in such a business usually are—it is very difficult indeed to detect anything amiss with them by even a moderately skilled person, and they therefore escape notice, as a rule. Veterinary surgeons, especially those in country practice, could do much in restraining this nefarious trade of the "dropped-meat" salesman; but a wide-ranging and systematic inspection of slaughter-houses and meat is the only sure safeguard for the public health. Of the prevalence of disease, parasitic and other, among animals whose flesh is consumed by man, we have ample evidence in the reports published periodically by the continental public abbatoirs, and there is no reason to expect that such disorders are less extensive in this country; while added to these we have the secret disorders—such as puerperal fever, anthrax, tuberculosis, swine-plague, &c.—which are not in evidence in these establishments, with the exception of tuberculosis, animals which are so affected, but are in good or fair condition, being often sent there for slaughter.

CHOLERA PROSPECTS.

CHOLERA is causing a good deal of anxiety to the Russian Government. The disease is stated to have broken out in Afghanistan as well as in Persia, and it is feared that it may make its way into the Transcaspian provinces, the sanitary state of which is deplorable. Owing to the filthy state of the irrigation canals and to the general neglect in Bokhara and Transcaspia it is believed that cholera, once imported, would spread both rapidly and in a virulent form. Hence a Commission of Prevention has been appointed, and it is stated that directly news is received to the effect that either Herat or Candahar is infected, prompt measures of control on the Russian frontier will be initiated. In the meantime, sanitary improvements, especially with regard to water-supply, are being undertaken. But these are hardly likely to be of much avail in the face of any immediate danger, for such works cannot be perfected at a moment's notice.

THE MEDICAL MISSIONARY.

THE truly philanthropic career which has just been cut short by the sudden death of the Rev. John Lowe, F.R.C.S. Edin., demands from us a word of recognition, not only of the man himself, but of the cause in whose service he lived and died. Mr. Lowe was a typical specimen of the medical missionary as that professional product is developed—to its honour be it said—so prolifically north of the Tweed. The son of a Congregational minister, he early saw where his true field of usefulness lay, and in qualifying for the combined work of body-healing and soul-awakening he showed by his zeal in study, both medical and theological, the high estimate he had formed of the vocation he had chosen for his own. The London Missionary Society was quite alive to his claims on its confidence when it sent him out some thirty years ago to work at the station at Travancore. Eight years' service there indicated him in March, 1871, as the proper man to superintend the Training Institution of the Edinburgh Medical Missionary Society—a post which he filled so well that in 1883 the Society made him its own secretary. His twofold work he continued to discharge with exemplary skill and devotion till 1890, when its increasing complexity induced the directors of the Society to give him an assistant superintendent in Dr. Hoernlé. With each successive year the institution scored fresh marks of efficiency; some notion of its progress may be inferred from the fact that, whereas in 1871 it had but seven students in preparation and an annual income of but £1476, it was able on its jubilee last February to announce that its male students alone numbered twenty-

Digitized by Google

nine, to say nothing of its lady novitiates; that fully seventy of its former students are at work on foreign stations; and that its yearly income is £6000. Nor is its expansion likely to stop there. It has outgrown its premises in the Cowgate, and is contemplating their enlargement by devoting *ad hoc* a portion of the jubilee memorial fund. To Mr. Lowe belongs great part of the credit of this most gratifying state of things, efficient as he was, not only in the professional qualifications aimed at by the promoters of the institution, but also in the spirit of work which produced an honourable emulation among its *personnel* and in that organising and administrative power which are themselves a rare and uncommunicable gift. No wonder that the sudden collapse at his post of so valuable a functionary should have impressed all friends of the medical missionary movement with something of a sense of personal loss. But his "work doth follow him," his example survives, and his masterly treatise on "Medical Missions, their Place and Power," enshrines the usefulness of the Edinburgh Society in a literary form, which has already carried its name and fame over the civilised world. Another publication of his, "The Life of Dr. Elmslie of Cashmere," is a beautiful tribute to a kindred soul, extinguished in sight of the richer harvest its philanthropic energy had prepared, and will in turn be followed by another biography still more inspiring to future labourers in the same humanitarian field—"The Life of the Rev. John Lowe, F.R.C.S Edin."

THE BRAVERY OF BRITISH WORKMEN.

HISTORY records the unselfish deeds and the bravery of our soldiers in time of danger, and future history will record the bravery of our workmen who earn their daily bread amidst great danger and imminent peril. An inquest was held last week by Mr. Bridghouse, county coroner, at Parr, near St. Helens, on a man named Richard Gill, aged fifty years. About a year and a half ago he was working in the shaft of a coal mine with three other men, blasting rock. The deceased, after the shots were ready, told the other men to get into the hopper. He then lighted the fuse connected with the shots, and then got into the hopper. He fancied he had given the wrong signal, and jumped out of the hopper to cut off the fuses. He managed to cut off one, but the others were too far burned. The other men begged him to give the signal to ascend and get into the hopper, but he said, "No, I will stay where I am. It is better for one man to die than for all." Just then the hopper began to ascend and the other men were drawn to the top, and soon after Gill pulled the signal wire and they went down to him and found him badly injured about the head. He had a compound fracture of the skull, and remained five months in hospital, but never got over his injury.

LONDON MEDICAL OFFICERS OF HEALTH.

WE announced last week that Mr. F. M. Corner had resigned the position of medical officer of health of Poplar for the reason that recent legislation, particularly the Public Health (London) Act, had so increased his duties that he could not conscientiously fulfil them. Mr. Corner's resignation is to be regretted, for his work in Poplar has been excellent, and under existing circumstances it cannot be expected that the district will be as well served as it has been in the past. The circumstances to which we refer are those which will place the public health service of London on a less satisfactory footing than it has hitherto been. While the duties of the medical officer of health have been added to year by year, and while the responsibility attaching to the office has greatly increased, the remuneration has either remained the same or has become still smaller. The result is that capable men with a sense of duty and responsibility will be driven from the public health service. However devoted they may be to that branch of the profession which aims at the prevention of disease, they have duties also to their families, and it will not be found that for merely nominal salaries they will undertake work which must make greater claims upon their time than is compatible with other work necessary for them to make proper provision for those dependent upon them. The public has to learn that in medicine as in other professions there are differences between those who constitute it, and it is certainly not to the advantage of the public service that it should be recruited from the ranks of those who would not be successful in its other branches. Men with skill and energy will find themselves debarred from entering one of the most useful branches of the profession. If medical officers of health are paid adequate salaries they can afford to keep their other work within limits; but at the present time nominal salaries are attached to the office, and it is expected that a large share of the officer's time shall be at the disposal of his authority. It has been urged that by reducing the salaries of higher officials, local authorities will be able to pay more liberal wages to the working men in its service. There is no one more desirous than ourselves that working people should be adequately paid, but we fail to see that this can only be brought about by reducing the scale of remuneration of an office requiring knowledge and ability which in other branches of the profession bring ample return. There is no class of the community more interested in the maintenance of an efficient public health service than the working people of London, and we do not doubt they would be the first to rebel at any failure to protect them from disease which is the result of an unwise parsimony. London can well afford to pay all its servants adequately, and certainly the difference between the amount of salary which is now paid and that which should be paid to the health officer is too trifling to affect the general question of the proper payment of working men.

MENTAL IMPROVEMENT AFTER TREPHINING.

THIS important subject is treated of in an article in a recent number of the *Medical News* by Dr. Hugo Engel of Philadelphia, with special reference to a case in which an operation of this nature was carried out. The patient was a boy fourteen years old, who was said to have been mentally bright and physically healthy until his sixth year, when he became subject to convulsions. These began one day without any apparent cause, and have never since ceased for any length of time. There was no family history of epilepsy or insanity, and there was no accident to account for the onset of convulsions. The fits had been becoming gradually more and more frequent, until at last he was having as many as twenty-one in twenty-four hours. But the interesting point is that the boy's intellect is said to have been, up to the time at which the fits commenced, of a higher order than is usually met with in a boy of his age; but since the fits began a gradual deterioration had been taking place, until he became dull and vicious, and finally seemed simple and almost idiotic and not unfrequently maniacal. There was a peculiar conformation of the skull, the appearance being as if it had been crushed in at the junction of the parietal and frontal bones, and Dr. Engel seems to have regarded this as the result of premature closing of the fontanelles and too early union of the sagittal and coronal sutures, and, from the effect of this on the brain apparently, he was in the state of extreme mal-development which he showed. Except that he was endowed with speech—of a guttural and monotonous character, it is true—he resembled a savage young

Digitized by Google

animal rather than a boy, in his behaviour generally. Under a systematic use of the bromides the convulsions became much less frequent and less severe, but no great change was evidenced in the mental condition, and it was decided to operate with the view of relieving the abnormal pressure on the brain, which from the conformation of the skull it was thought must be present. Two operations were carried out by removing portions of bone from the right frontal and parietal bones immediately contiguous to the coronal suture. The second operation was carried out after an interval of three months had elapsed from the first. For five weeks after the first and for two weeks after the second operation he had no attacks, but after that they increased in frequency, but never became so frequent as before, while their character was very much changed, so that instead of severe convulsions with clonic spasms, he now had attacks of loss of consciousness, with slight twitchings. But the chief improvement was in his mental condition, and from an idiotic, sulking savage he developed into a bright, lively, and good-natured boy. His former irritability and moroseness were replaced by good-nature, and now, to all inquiries, he made intelligent replies, whereas formerly he only sulked when asked questions. He also expressed a wish to go to school, and his perception was wonderfully quickened, so that a complete change was the result of surgical interference in this case. Such a result is, of course, extremely significant; but it remains to be seen in what cases operative measures are likely to effect so much as they apparently did in this case. But at least Dr. Engel and his surgical colleague, Mr. Packard, are to be congratulated on the brilliant success which followed interference in a case which could not, even to the sanguine, have appeared very promising.

THE STRUTHERS TESTIMONIAL FUND.

WE understand from Dr. James Anderson, the secretary and treasurer of the Struthers Testimonial Fund, that Sir George Reid, P.R.S.A., has now finished his portrait of Professor Struthers, and is at work on the replica for Marischal College, Aberdeen. It is proposed that the portrait should be presented to Professor Struthers on Wednesday, May 18th, at 4.30 P.M., by Sir Andrew Clark, Bart., at 16, Cavendish-square. A photo-engraving of the portrait will be prepared, under Sir George Reid's supervision, by Messrs. T. and R. Annan and Sons, and will cost, for subscribers, half a guinea; for non-subscribers, a guinea.

THE INTERNATIONAL HORTICULTURAL EXHIBITION.

THE Duke of Connaught, who was accompanied by the Bishop of London and Mrs. Temple, Lord Ashbourne, Lord Rowton, and Sir G. Baden Powell, formally opened the Horticultural Exhibition at Earl's-court on Saturday last, May 7th. The weather, inasmuch as it was all that could be desired—a bright sunny day—it may be hoped will augur well for the future success of the undertaking. The beauty of the subject of the exhibition is one of course which must appeal to everyone. Horticulture is both science and art, and it is illustrated with such consummate skill and excellent taste that the exhibition at Earl's-court is certain to please as well as educate. The growth and development of the horticultural art in this country from Tudor times to the present is fully demonstrated, and gardens of the Continental and Eastern type, both of ancient and existing periods, are exquisitely modelled. In one very effective grouping is shown a well-contrasted display of the horticultural products and characteristics of ancient Rome, of the Tudor days, of modern Italy, of ancient Egypt, of Jacobean times, and of India, Japan, and China; while a very extensive collection of the flowers, plants, trees, and shrubs of the present day gives an admirable representation of the Victorian era. Altogether the exhibition compares very favourably with its predecessors, and, judging from our inspection on Saturday last, the promoters have certainly at their disposal all the means to provide liberally for the healthy amusement and recreation of the visitors.

DEATH UNDER CHLOROFORM.

OPERATIONS about the mouth and naso-pharynx have their peculiar dangers and difficulties, not only on account of the operative measures themselves, but also from the extreme care with which the anæsthetic requires to be given. Unfortunately, these points were illustrated by a death which took place at the Hospital for Diseases of the Throat on Saturday, April 30th. The patient, a boy aged twelve, suffered from a polypus in the ear, as well as a throat affection, and it was decided to give him chloroform, as the operator, Dr. J. W. Bond, stated ether would produce more bleeding, and some general anæsthetic was necessary owing to the painful character of the operation. The removal of the polypus was effected, and the operator noticed that respiration had ceased. Artificial respiration, promptly performed, failed to resuscitate the boy. At the necropsy, the report states, the heart was found to be enlarged, and had a larger quantity of fat upon its surface than is common at so early a period of life. The report before us does not say who was the administrator, nor does it mention the posture of the patient. These and other points are too often omitted in the evidence given before coroners, and when not supplied are not always obtainable subsequently.

A NEW USE OF THE TITLE M.B.

AT an inquest at Hull by Mr. Thorney, the borough coroner, it transpired that the patient had received medicines from a person named Priestley, who used the letters M.B. after his name. Mr. Priestley meant by this "medical botanist." The coroner said Mr. Priestley had no right to attach the initials after his name when he knew they meant something else. We think that a more seriously false and misleading use of medical titles could not well be imagined.

TUBERCULOCIDIN.

SINCE the announcement made by Koch, more than a year ago, that he had discovered a substance which had a selective action on tubercle, many observers have been working on the properties of this substance which he named tuberculin. Foremost among such has been Klebs. In the *Deutsche Medicinische Wochenschrift*, 1891, No. 45, he reported that by precipitation with platinum chloride and the so-called alkaloid reagents he was able to separate from tuberculin an active principle, which he termed alexin or tuberculocidin, which has the same action on tubercle that tuberculin has, but without causing the depression produced by it. Klebs has since published a monograph on the subject—"Die Behandlung der Tuberculose mit Tuberculocidin"—of which a short abstract is given in the *Medical News* (New York) of April 16th, 1892. Klebs believes that the efficacy of this substance depends upon an influence exerted on the tubercle bacilli, resulting in their degeneration. Thus large doses, by causing rapid disintegration of tuberculous tissue, produce some elevation of temperature by a form of auto-inoculation with tuberculin. Tuberculocidin does not cause necrosis of the affected tissues. The process appears to be one of involution associated with exudation. That this body is not merely an attenuated form of tuberculin is demonstrated by the fact that although the former represents by weight one-fortieth of the latter,

Digitized by Google

an injection of a decigramme (0·1) of the one is followed by no elevation of temperature, while an injection of two milligrammes and a half (0·0025) of the other is followed by febrile reaction. In man the initial dose of tuberculocidin is about two milligrammes (0·002); if this occasions no unpleasant manifestations, the dose is rapidly increased to a decigramme (0·1), or a decigramme and a half (0·15). Hectic fever is no counter-indication—in fact, energetic treatment may cause its disappearance. The injections should be made daily for a month, and then intermitted for the same length of time, to be resumed or not according to the indications present. When urgent symptoms occur other therapeutic measures may be advantageously employed in conjunction with the injections. Nearly a hundred cases, principally of pulmonary tuberculosis, have been treated with tuberculocidin. Of seventy-five, in which a reasonable time had elapsed, fourteen appeared to have been cured, forty-five were improved, fourteen remain unimproved, and two died. Complications were universally absent. Such results are certainly encouraging; but after recent experiences medical men are naturally sceptical about accepting as an absolutely curative measure the treatment of tuberculosis by injections of substances allied to tuberculin. Many, however, are still of opinion that the reaction against Koch's method of treatment went too far, and much interest will be felt in watching the outcome of the numerous investigations now in progress that have for their object the treatment of such a widespread disease as tuberculosis.

REMUNERATION OF HEALTH OFFICERS.

THE attitude taken by the Local Government Board as to the salary of the East Barnet Valley medical officer of health has in the end resulted in a satisfactory arrangement. That Board held that a salary of some £30 was insufficient, and they refused to certify for repayment of one half of it out of the county funds. Later on the salary was somewhat raised, but now the local board have determined to pay a sum of £75 yearly and to ask for repayment. In doing this they testify that they are influenced by the extremely satisfactory and efficient manner in which Mr. Roughton has performed his duties.

MEDICAL LEGISLATION IN NEW SOUTH WALES.

IN medical legislation it is impossible to please everybody. The discussion now going on in the public papers of the colony shows this, and exhibits a strange variety of views even in those who might be expected to think alike. One man is sensible in nine points, and very unsatisfactory in his tenth. Fortunately, public opinion everywhere is in favour of legislation that enables the public to distinguish the qualified from the unqualified; and there is scarcely less unanimity in favour of giving power to bodies and to the medical councils created by such legislation to preserve a certain tone and standard of professional ethics. There are exceptions, however, even here, and we are astonished to find men who write sensibly and have good qualifications speak lightly of the disciplinary powers of the medical authorities. A practitioner, writing in the *Sydney Morning Herald* on the Medical Bill, objects mainly to the fact that in the Medical Council it creates there is no direct representation of the profession. The Council is to consist of ten members, five appointed by the governor and five by the Senate of the University of Sydney. We entirely agree with him in this objection. There ought to be a substantial representation in the Council of the registered practitioners of the colony, and no Council can be considered final or satisfactory which does not contain such an element. By all means this defect should be remedied. On the other hand, the writer's views are very unsatisfactory in regard to the disciplinary powers of the Council. "No medical man should be punished for acts which are not a violation of the laws of the land." "The Council should not be allowed to wander out into the shady lands of professional etiquette." We do not approve such sentiments. They are opposed to the whole spirit and tradition of the profession, and, we may add, to the whole interest of the public. The profession has its own refined duties and its own refined laws. The next sentence is significant. "The standard of professional etiquette in these colonies is just as low as it well can be." Is not this admission the very proof that other laws are wanted for the regulation of a high profession than the mere laws of the land. We trust that such views will not prevail. The duties of medical men are of the most delicate kind. Fraud and imposture and worse are very possible under cover of its functions. *Corruptio optimi pessima.* And the medical profession owes it alike to itself and the public to have a standard of morals equal to its standard of duty.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE second course of lectures at the Royal College of Surgeons will be given in the theatre of the College at 4 P.M. during the remainder of May and June as follows:—Dr. J. Rose Bradford will deliver three lectures on the Physiology of the Vaso-motor System on Monday, May 23rd, Wednesday, 25th, and Friday, 27th. Professor C. W. M. Moullin will give three lectures on the Operative Treatment of Hypertrophy of the Prostate on Monday, May 30th, Wednesday, June 1st, and Friday, June 3rd. Professor H. B. Robinson will give three lectures on Certain Diseases of the Breast on Tuesday, June 7th, Wednesday, 8th, and Friday, 10th. Professor W. Watson Cheyne will deliver three lectures on the Treatment of Surgical Tubercular Diseases, on Monday, Wednesday, and Friday, June 13th, 15th, and 17th. Professor H. T. Butlin will give three lectures, on Monday, Wednesday, and Friday, June 20th, 22nd, and 24th, on Cancer of the Scrotum in Chimney Sweeps and others.

MEDICAL ESTIMATE OF ALCOHOL IN NEW YORK.

THERE seems to be a decided wish to summarise the opinion of medical men on the momentous subject of the habitual use of alcohol. Several attempts of the sort have been made in England. None of them have been satisfactory. There has been an air of insincerity in many of them, the names of physicians who were known to be non-abstainers themselves being often paraded as censors of the public in its use of alcohol. Besides, it is impossible for physicians in a small space to express themselves on such a subject without danger of being misunderstood—in other words, without the public misapprehending the import of their testimony. Moreover, this is eminently a question where opinion should be weighed as well as counted. Those who are most ready to give an opinion, and most dogmatic and positive in its expression, are often of least authority in the matter. We have before us, in a supplement of *Frank Leslie's Weekly*, the result of an attempt to ascertain the opinion of every medical practitioner in New York. Every physician was asked to reply to the question, "Is the moderate use of wine and beer injurious to the health of grown persons?" By dint of importunity, and putting the question over and over again to the 2900 physicians practising in New York City, 675 replies only have been received. Less than a fourth have yielded to the temptation to see their opinions in print. The answers are described under the following heads—negative 435, semi-negative 88, affirmative 152—that is, that the largest number do not believe that the moderate use of wine and beer is injurious to the health of grown persons.

Digitized by Google

There is every variety of opinion and every qualification of opinion expressed. Thus one gentleman thinks that no alcohol should be allowed under any circumstances, except on the advice of at least two physicians. This same gentleman adds: "I would not advise with any physician that I knew was in the habit of drinking wine or beer habitually." On the other hand, a physician, nearly eighty years of age, has taken wine from his childhood, and says: "I was well acquainted in Hungary with a physician 106 years old who was able to visit patients and give a very good lecture on materia medica. He drank wine twice daily, eight ounces each time, and I have heard him say many times that without wine he would not live a minute." There is to discriminating readers interest even in opinions which are extreme. But we are inclined most to praise the 2225 physicians who withheld their opinion, agreeing with a practitioner who replies "that voting on scientific questions is harmful to science and truth; scientific problems cannot be solved by majorities." The reasons for total abstinence must be found in other than medical considerations. But while we doubt the wisdom of medical men giving a rounded opinion on so large a question for popular use, we cannot too strongly emphasise their responsibility in reference to it, and the importance alike of their prescriptions and their example. There are many drugs which are apt to be continued after the need for them has passed away. The same is true of diet. And the physician is apt to find the patient, whom perhaps he has saved from death by the timely use of alcohol, persisting in its use months after the conditions which indicated its employment have ceased.

THE VACANT CORONERSHIPS FOR THE NEWINGTON DISTRICT AND WESTERN DIVISION OF THE COUNTY OF LONDON.

IT has been stated in a leading daily paper that the vacancy for the coronership caused by Mr. Carter's death will not be filled up by a new appointment, but by dividing the Newington district into three portions, giving one to each of the three coroners for neighbouring districts, Mr. Braxton Hicks, Mr. Wyatt, and Mr. Carttar. It is also stated that the division over which the late Dr. Diplock presided as coroner is to be divided into two—the London, or larger portion, and the Middlesex, or smaller one. Whether these statements be correct or not, remains to be seen; but whether there will be one, two, or three vacancies, one thing is clear—viz., that there is no dearth of most eligible medical candidates. Dr. W. Wynn Westcott comes forward with such qualifications for the office as have rarely ever been possessed by any previous candidate for this or any other vacant coronership. He has been deputy coroner to Dr. Danford Thomas for the last nine years, and during that time has held over two thousand inquests. His medical qualifications are those of M.B.Lond., M.R.C.S.Eng., and L.S.A., which were obtained twenty-two years ago, in addition to which he has made special studies of forensic medicine, public health, criminal laws, and the laws of evidence. He has also worked at practical analysis at the College of State medicine, and among other contributions to medical literature he has published "A Coroner's Notes on Sudden Death," "The Bloomsbury Mystery, a Medico legal Essay," and "A Summary of Deaths in London Caused by Excess of Alcohol." Dr. Westcott has unexceptionable testimonials from Dr. Danford Thomas, Sir Andrew Clark, Sir Henry Thompson, Drs. B. W. Richardson and G. V. Poore. Should the members of the London County Council decide to elect him to one of the vacant offices, they will do credit to themselves and be consulting the public interests. Dr. Luxmore Drew has also very high qualifications for the office of coroner, being a barrister in addition to possessing excellent medical qualifications and testimonials. Dr. Grierson Gledhill is a barrister and member of the Northern Circuit, as well as a Bachelor of Medicine, Master of Surgery, &c. Dr. Bernard O'Connor also possesses legal and medical qualifications, being a Doctor of Medicine, Member of the Royal College of Physicians, London, as well as Barrister-at-Law of Gray's Inn, Middlesex, and North London Sessions and Central Criminal Court. Dr. G. E. Yarrow, barrister-at-law, is also an applicant for the vacant coronership. It is to be hoped that the electorate will take notice of this desire on the part of medical candidates to acquire legal qualifications, so as to make themselves doubly eligible, and to satisfy those many persons who think that the coroner should possess a legal training. Barristers and solicitors have not shown themselves equally anxious to satisfy the public in the much more important qualification of a medical training, probably because the study o anatomy, pathology, and the numerous subjects of the medical curriculum, requires much more self-denial and patience than the training for the bar. Mr. Leonard Bramah Diplock, L.S.A., son of the late coroner, and Dr. George A. Bateman, honorary secretary of the Medical Defence Union, are also medical candidates for the vacancies, the latter having been a student for the bar. Probably other medical candidates may come forward, but in any case it will be clear from the foregoing that the London County Council will not have any want of eligible medical candidates whose claims to the office over merely legal candidates do not admit of argument, being irresistible. And now that they have satisfied the public prejudice by acquiring legal qualifications, there remains no justification for their claims being overlooked. Each county councillor should be individually informed of the paramount claims which members of the medical profession have for the office of coroner.

COLOUR PHOTOGRAPHY.

THE beautiful process of colour photography, briefly alluded to in the article on the conversazione of the Royal Society in our last issue, is doubtless an important step, in one direction, towards attaining the reproduction of colour by means of the camera, and as the subject is one of very general interest we give a few more facts concerning Mr. Ives' ingenious method. Mr. Ives prepares, by means of a compound camera front, three photographic negatives of the object by simultaneous and equal exposure, from the same point of view and upon the same sensitive plate. The photographic plate is sensitive to all colours of light; but by interposing certain media or light filters one of the negatives is produced by only such light rays as excite in due proportion the fundamental red sensation; another by light rays as they excite the fundamental green sensation; and another by light rays as they excite the fundamental blue-violet sensation. From this triple negative a corresponding triple lantern slide may be made, which, although it shows no colour in the ordinary way, contains such a graphic record of the natural colours that in order to reproduce them to the eye it is sufficient merely to superpose the three images, one with red light, one with green, and one with blue-violet. This is accomplished either in Mr. Ives' new helio-chromoscope, a device about the size and pattern of a hand stereoscope, and used in much the same way, or by projection with a special form of optical lantern, having three optical systems with red, green, and blue glasses. The three images, being exactly superposed, appear on the screen as one only, in which the natural colours are faithfully reproduced, together with the light and shade. Images of three ordinary photographs, exactly alike, if superposed in the same way, through the same

Digitized by Google

coloured glasses would show no colour whatever. Although it would appear that photographic prints cannot easily be obtained by this process, yet the fact that pathological specimens, for instance, may by this means be projected on the screen with the original colours, all faithfully portrayed, will doubtless afford exceptional aid to the demonstrator. The process will also render signal service in other departments of scientific research.

THE SPREAD OF SMALL-POX.

AMONGST the localities newly infected with small-pox we hear of a few cases at Acton, and of an outbreak at Denaby Main near Doncaster, where two cottages have been turned into a hospital. The disease is still maintained in the Dewsbury district, and cases remain under isolation at Yarmouth, at Pembroke Dock, at Liverpool, and other places. In short, the somewhat wide distribution of the infection necessarily causes anxiety both as regards the immediate future and perhaps still more so as regards the prospects of an exacerbation later on, even if the present season is got over without any further diffusion of infection.

TOBACCO-SMOKING AMONG BOYS.

As long as the habit of tobacco-smoking remains a common practice among men, so long may we expect that the boyhood of the time will acknowledge its fascination. It is therefore in a sense as natural as it is morbid that the soothing weed should be numbered among the mischievous absurdities of growing youth. This is much to be regretted for several reasons. Constitutionally, the boy is not even a lesser man. Between his young and vigorous nervous system and that of the male adult there is this essential difference—the one is developing, the other formed. Endowed with greater elasticity, the former is also in proportion less stable, and such effects as the narcosis of tobacco cannot at all assist, but must more or less pervert, its normal activity. The man's more settled nerves are less affected. Then with boys the smoking habit is, in its way, a first love, and as such is almost certain to be indulged to excess. The circulatory and nerve structures are overworked in consequence, digestion suffers, and, whatever may survive of physical energy, we have often to note a decrease in constitutional soundness. Influenced, no doubt, by such reasons as these, and others of more general and social significance, the medical faculty in Manchester, in reply to a circular issued by the Anti-Tobacco League, have set themselves to seek a mitigation of the foolish evil. Their recommendations follow much the same line as that adopted by the Manchester Conference a year ago, in advising the suppression by law of smoking among boys under sixteen years of age. The well-known example of Germany in this matter is worthy of general imitation. It has already been reproduced (*vide* THE LANCET, Aug. 25th, 1890) in the State law of New York, boys under the said age being forbidden to smoke in public.

SENSATIONAL EXHIBITIONS.

THE miserable fate of a man who died recently in the City Hospital, St. Louis, U.S.A., might be noted with profit by the more daring class of professional jugglers. In this case the offence against which nature ultimately rebelled with fatal energy consisted chiefly in a habit of swallowing nails, tacks, and pieces of glass. The "freak of nature" was also a famous heavy-weight lifter, and even went the length of sustaining the weight of a horse weighing 1050 lb., which traversed a plank laid across the chest. After some six years of tack-eating the unfortunate performer was seized with persistent vomiting, probably not the first attack of its kind, with progressive signs of collapse, and died in four days, notwithstanding the removal by operative measures of a quantity of the unnatural diet above mentioned. A post-mortem examination revealed the presence in the œsophagus, stomach, and intestines of several ounces of glass and tacks, the mucous membrane being also extensively ulcerated. We have repeatedly expressed our disapproval of the exhibitions offered to satisfy a morbid public taste for the extraordinary by professional sensation-mongers. It is not often, indeed, that an opportunity occurs for demonstrating so exactly as in the case just recorded the fallacy of such performances and their frequent deadly significance as regards the exhibited wonder. We quote this fresh example of its kind as conveying in its most forcible form a proof that these exhibitions are still far too little subject to the control of police authorities, and that no pretext of public expediency or personal liberty can excuse practices which are frequently nothing less than suicidal.

SEX AND MUSIC.

SIR J. CRICHTON-BROWNE'S oration before the Medical Society has been read with interest far beyond the circle to which it was immediately addressed, having penetrated to quarters usually impervious to physiological enlightenment and hygienic remonstrance. No need, therefore, to apologise for returning to it, charged as it is with an educational value which re-discussion will be found to strengthen, certainly not to impair. Even before the differences between the sexes in cerebral structure and function were so scientifically demonstrable as now, there were practical tests in the sphere of education itself which pointed irresistibly to the conclusion arrived at by the medical orator. Take, for instance, the art of music. There is no room here for the contention that, as compared with the boy, the girl has not had fair play—that opportunities for cultivating the art have in her case been few, in his case many. The reverse is the truth. If there is a branch of education in which girls have been schooled to the neglect of every other, it is precisely that of music. It is among the primary subjects to which she is put, and among the very last she is allowed to leave off. Not one hour a day but many hours out of the twenty-four are consumed by her at the piano, to say nothing of other instruments, while singing lessons are usually given in supplement to these. It might have been thought that if practice gives perfection woman would have excelled her male counterpart not only as an executant but as a composer. But what are the facts? In instrumental performance she cannot for a moment compare with him, while as to composition she is nowhere. The repertory of music from the dawn of the art to the present day owes simply nothing to her. Considering the time she has spent over it, her failure to evolve new harmonies or even new melodies is one of the most extraordinary enigmas in the history of the fine arts. It has been remarked, but never explained, by such accomplished æsthetic writers as Lady Eastlake in her celebrated essay on "Music," and by such keen psychological analysts as Mr. G. H. Lewes in his "Life of Goethe"; it is, indeed, a problem still awaiting solution, unless we can solve it by an appeal to such facts as Sir J. Crichton-Browne adduced in his recent oration—the inferiority of woman to man in the cerebral substratum of ideo-motor energy. Why with such a record of "no results"—so far, at least, as the production of a female Handel or Beethoven or even a female Glück or Bellini is concerned—music should usurp such a preponderant place in girls' education it is difficult to divine. We have seen the practice defended on the same grounds on which in our classical schools the writing of Greek and Latin verse is vindicated: a finer appreciation is thus attained, in the girls' case, of musical

Digitized by Google

excellence, in the boys' of the Hellenic and Latin masterpieces. "'Tis better to have tried and failed than never to have tried at all," while failure gives a truer sense of what perfection consists in. Such is the argument—for what it is worth. But even on this analogy the boy sometimes succeeds where the girl invariably fails. In George Buchanan, John Milton, Arthur Johnston, Joseph Addison, Vincent Bourne, Thomas Gray, to say nothing of the late Marquess Wellesley and Benjamin Hall Kennedy, we have classical poets hardly inferior to any but the best of antiquity; but where, in ancient times or in modern, can woman, with all her practice, be found to have created one *chef-d'œuvre* in music? The inference implied by the negative answer to such a question seems simply this: that in the higher efforts of mind—even in those where the admixture of an emotional element, as in music, might be supposed to give her the advantage—woman is inferior to her male counterpart, and cannot by any educational forcing system be made to equal him—deficient as she is in the physiological conditions of ideo-plastic power.

CHOLERA IN INDIA.

THERE does not yet appear to have been time to furnish any statistical summary of the results of the progress of cholera in India in connexion with the late outbreak of that disease at Hurdwar. The fair at that place this year does not seem to have been one of the largest of the kind. The great fair, which occurs once in twelve years, took place last year; and, whether owing to the admirable sanitary arrangements made by the Government or not we cannot say, no epidemic then took place like that which has occurred in the smaller gathering of the present year. According to the latest reports from India there had been up to April 13th last seventeen deaths from cholera out of twenty-seven attacks on the road to Simla, which place is the seat of government during the hot season. The disease appeared at Meean Meer, and it is stated to have caused a considerable exodus from that place. Cholera broke out in the 16th Bengal Cavalry—three cases and one death occurred in one day—and the medical officer rejoined his regiment at Meean Meer from cave. According to a telegram of the 11th inst. from Simla, epidemic cholera is raging at Cabul, and the Ameer is encamped outside the city.

"OUR GIDEON GRAYS."

THE memorial erected on Tuesday last to the late Mr. Joseph Tonks, M.R.C.S., at Willenhall comes to remind a preoccupied world of the heroism that often links itself to the unobtrusive career of "our Gideon Grays" in town as well as country. Here was a general practitioner, able and accomplished in his profession, who was content to live and labour among the poor of a populous neighbourhood, and,

Nel mezzo del cammin di nostra vita,

to go down to a premature grave with no other reward than the silent tears and the scarce audible blessings that well up from hearts rich in nothing but gratitude. Mr. Tonks was peculiarly the "poor man's doctor"—not, as the cynic would put it, that he was "good enough" for a humble *clientèle*, but in the sense that "he knew his art but not his trade," as Swift said of Arbuthnot, or, as a still earlier moralist, embodied it in verse—

Homo sum: humani nihil a me alienum puto.

In one of the least happily inspired effusions of the Poet Laureate he draws a picture of a coarse, unfeeling martinet of a practitioner whom even infantile suffering could not soften, and who carried the spirit of the experimenter or the laboratory student into the "homes where poor men die." Such a medical monstrosity may have existed in Lord Tennyson's experience, for no profession is without its unworthy representatives; but the portrait was manifestly nothing more than a caricature—to be atoned for by a counter-presentation, such as few of our towns or villages could fail to furnish, in which the poet would do not more justice to the profession he has maligned than to his own genius, that had stooped to the exceptional in life and the inartistic in inspiration. "Look on this picture and on that," he might well enable his readers to say, by contrasting with his caricature, the portrait of a hero, so humble and yet so high, as the "poor man's doctor" of Willenhall. Few more touching narratives have come before us than that of the ceremonial of Tuesday last, when every approach to the monument about to be unveiled in remembrance of Mr. Tonks was densely packed by multitudes anxious to pay the tribute of their presence at the unveiling of a memorial which their pennies had defrayed. Not by the gold and silver of the rich, as the spokesman of the occasion said, but by the infinite multiplication of the poor man's copper and the widow's mite had the memorial fund been subscribed, until the monument itself had reached an amplitude that, seconded by artistic design and execution, made it, as Mr. Lawson Tait, who worthily performed the ceremony of unveiling, observed, "a work of art in a community where works of art were not too common." The artistic sense may, indeed, be gratified, and, among the appreciative few be refined and stimulated by a public monument like this; but its true function will be to keep prominent before the people the beauty and nobility of a life that marched to the

Still, sad music of humanity,

until, prematurely it may be, but ripe and rich in performance, it closed amid the blessings of the community on which its best energies were expended and to which its example is bequeathed.

THE SANITARY STATE OF MONMOUTH.

WE are glad to learn that the Town Council of Monmouth have decided to carry out an efficient system of drainage for the borough. We have had to refer to other sanitary defects in Monmouth than those that can be remedied by sewers, but the action decided on indicates a determination to move in the right direction, and it is to be hoped that such matters as slaughter-houses, piggeries, &c., will not be allowed to continue sources of nuisance in a town the sewerage of which is to be placed in a satisfactory condition.

THE DENTAL HOSPITAL OF LONDON.

WE understand that the Dental Hospital of London is contemplating moving to a new site as soon as the money is forthcoming. The sum required will probably be about £40,000. Promises have already been received from the medical staff and friends of the hospital to the amount of about £3000, and as soon as £20,000 is collected to purchase a suitable site a new building will be started. The present hospital, which has for many years so ably fulfilled its duties, has, with the increasing number of patients and students, become too small for present requirements. It was hoped that some portion of premises at the back of the present hospital could be acquired, but this is now impracticable, and it is therefore only possible to provide an adequate building both in relation to area and proper equipment in every department by obtaining a piece of ground with larger area. In the days when Sir Edwin Saunders so generously provided £5000 towards moving the hospital from Soho-square to its present site there was probably an entry of about ten students a year, while at present the entry is over fifty. It is manifest that even with the recent addition of a small house that the accommodation at present is a little cramped, while at the rate gentlemen are re-

Digitized by Google

gistering as dental students much greater area will be required to provide a sufficient number of chairs. From the fact that this hospital is for the treatment of the teeth only, it does not, perhaps, receive that support from the public it deserves. To carry on a dental hospital the annual expenditure is necessarily large for the materials used, and, notwithstanding the fact that the teeth are considered of trifling importance, there is no doubt they are serious factors in the general welfare of the public. Much local and constitutional troubles would be saved were the public really careful about the sanitary condition of their mouths.

EXPERIMENTS WITH SNAKE POISON.

WE gather from a late number of the *Pioneer Mail* that an opportunity has arisen—in connexion with the construction of a new and improved snake-house at the Calcutta Zoological Gardens, which will contain specimens of all the principal poisonous snakes in the country—of making experiments in a systematic manner with snake poison for scientific and practical purposes. Considering the loss of life in India attributable to this cause, it is a matter for the Imperial rather than for any provincial Government of that country to take up, and the Lieutenant-Governor of Bengal has, it is understood, addressed the Government of India on the subject. It is proposed to fit up a small laboratory in connexion with the snake-house for the purpose of prosecuting inquiries bearing upon the pathology of snake bite and cognate subjects, and of testing by experiment the various alleged remedies for snake bite which are from time to time brought to notice. The Calcutta Zoological Gardens would offer opportunities for instituting such inquiries which probably could not be had anywhere else in the world; and Surgeon-Major D. D. Cunningham, who is eminently fitted for organising and initiating such a work, and is president of the committee of the Zoological Gardens, will, it is believed, be willing to render effective aid in the matter.

LONDON DUST REMOVAL.

THE vestries and district boards in London are constantly threatened with new dangers. The Public Health (London) Act must have caused some anxiety to those who regulate our local affairs, especially the provision which enables the householder to recover a penalty of £20 from the sanitary authority if the latter neglect to remove his house-dust within forty-eight hours after written notice. A householder in the Strand has, however, adopted a course which has been more disastrous to the sanitary authority than the infliction of any penalty permitted by the Public Health Act. He had been for some time at variance with the authority as to the removal of his house dust. He had visited the offices of the board, and had been promised that the dust collector should pay a weekly visit to his house for this purpose; but this promise had not been kept, and he had constantly either verbally or by letter applied to the board or its solicitors, or clerk, or surveyor, but without satisfactory result. In June of last year he applied to Mr. Vaughan of Bow-street, and was told that a warrant should be issued if the matter was not attended to; and finally, having suffered from a swollen and relaxed throat, and a mild form of inflammation of stomach and intestines, he had been obliged to leave his home and travel, and he now brought an action to recover damages from the Strand Board of Works for "alleged refusal and neglect to collect and remove his house refuse, whereby the malodorous smell caused him serious illness." Two medical men were called, and gave evidence as to the plaintiff's condition before he left London, and they attributed his illness to the smells from decomposed animal and vegetable refuse in the dust-bin. Among the points of interest raised in the hearing of the case were two—one, the statement that the plaintiff was unable to avoid throwing kitchen refuse into the dust-bin, because at times he had only a gas fire in use; the other, the contention of the sanitary authority that, having contracted for the removal of all the refuse in the Strand district, it was relieved of liability in the matter. Upon the latter point Mr. Justice Grantham decided that this objection could not be accepted. Finally, the plaintiff was awarded £75 damages. We trust that this case will be carefully studied by every sanitary authority in London, and that some better effort will be made than heretofore to bring about a more complete system of refuse removal. Householders may regard with satisfaction the refusal of Mr. Justice Grantham to allow a sanitary authority to disclaim liability for omissions on the part of its contractors.

ISOLATION AT CARDIFF.

THE conflict of opinion as to the duty of dealing with infectious disease in the case of persons who are either actually destitute or bordering on destitution when sick has been significantly illustrated in the case of a commercial traveller at Cardiff, who claimed from the guardians a sum of money for the maintenance of two fever patients who were lodgers in his house, and who were actually relieved by the relieving officer. He added that he sought to get the cases removed to the workhouse, whereupon, according to the local press, "the medical officer threatened to institute proceedings against him if they were ejected, there being no proper accommodation for them in the town." The case was decided against the plaintiff. There is, indeed, no obligation upon Poor-law guardians to provide for the infectious sick; they have a duty as to maintaining the destitute, but no duty as to the accommodation of even the infectious sick in such a way as to protect the community against the spread of infection. The Public Health Act, 1875, has imposed the latter duty on the sanitary authority, quite irrespectively of the position of the sick person as to destitution. These cases of conflict always arise in towns and districts where the sanitary authorities have failed to make proper provision for the isolation of infectious cases, and it is by no means creditable that a large and important borough like Cardiff should have been content to remain so long without such elementary means of protecting the public health.

GLASGOW UNIVERSITY CLUB.

THE Glasgow University Club met on Wednesday, May 4th, at the Freemasons' Tavern, under the presidency of Lord Shand. Among those present were Lord Kinnear, Mr. James A. Campbell, LL.D., M.P., Mr. Walter Severn, R.C.A., Professor G. G. Ramsay, Professor J. M. Thomson (honorary treasurer), Mr. J. R. McIlraith (honorary secretary), Dr. Heron, and others. Lord Shand intimated that letters of apology had been received from Lord Watson, Sir George H. B. MacLeod, Lord Kelvin, Principal Caird, Canon Ainger, Professor W. T. Gairdner, Lord Stair, &c. His lordship then proposed the toast of "The Queen" in appropriate terms, and subsequently "The Glasgow University Club, London." Lord Kinnear proposed the toast of "Our Alma Mater," and Professor G. G. Ramsay, replying thereto, remarked that Lord Kinnear, in proposing the toast, was very like an executioner proposing the health of his victim, for he had taken a chief part in the great reforms which would shortly take effect in the University. Mr. George Lillie Craik proposed "The Guests," coupling this toast with the name of Mr. Walter Severn, President of the Dudley Gallery, who replied; and the proceedings were brought to a close by Mr. James A. Campbell,

Digitized by Google

M.P., proposing "The Chairman, Lord Shand." For the information of those of our readers who are connected with the Glasgow University we may mention that the secretaries of the club are Professor D. W. Finlay, M.D., F.R.C.P., The College, Aberdeen, and Mr. J. R. McIlraith, M.A., LL.B., Barrister-at-law, 4, Harcourt-buildings, Temple, London.

INFANTILE CEREBRAL PALSY.

IN an article in the *New York Medical Journal*, dealing with the pathology of infantile cerebral palsies, Dr. Sachs describes two necropsies which he has made in cases of this nature. The first case was that of a boy with a condition of old spastic hemiplegia, who died suddenly with symptoms of basal mischief. A large cyst was found accounting for the old condition, while internal to the cyst and at the base small-celled sarcomata were discovered as the cause of the sudden fatal termination. The second case was that of a one-year old child, cyanotic at birth, who suffered much from cramps, and whose mental development was poor. In the intervals of the cramps a spastic condition of the legs was evident. Examination revealed a condition of chronic meningo-encephalitis with secondary degenerations in the spinal cord. The origin of the cerebral condition Dr. Sachs ascribes to a widespread subpial hæmorrhage occurring during a protracted labour. As regards the question of operative procedure, he is of opinion that in cases of acquired and not too widespread cortical disease such interference may be useful, and that if it is to be carried out it should be done as quickly as possible on account of the rapidly occurring secondary degenerations. The difficulty in cases which clinically fall into this category is one of diagnosis, and even approximate certainty (a *sine quâ non* if operation is to be proposed) can only be attained after careful and extensive observations, both clinical and pathological, have been made. To such observations Dr. Sachs' contribution is a valuable addition.

VACCINATION INJURIES.

A TYPICAL CASE of an allegation as to injury and death brought about by vaccination has occurred at Oldbury, where a coroner's inquest was held to inquire into the circumstances. The father held that the child had not been well since its vaccination, but the mother frankly admitted that before its death, the child's vaccinated arm had been well for no less a period than one month, and that for some weeks it had failed to take its nourishment properly, in consequence of which she put it out to nurse with a neighbour. The medical evidence was to the effect that the infant was not properly cared for, that it did not receive proper diet, and that it died in a convulsive fit. The suggestion of Mr. Grant, who represented anti-vaccination principles, was to the effect that vaccination must be regarded as an indirect cause of death. Indeed, it seems to be a creed of that party that if subsequently to vaccination any harm occurs, then *post hoc ergo propter hoc* must apply; but if any good comes whether by way of saving life from small-pox or otherwise, the results are quite accidental, and are not worth recording.

FOREIGN UNIVERSITY INTELLIGENCE.

Boston (Harvard).—Dr. R. H. Fitz has been appointed to the chair of Medicine.

Buda Pesth.—Dr. E. Schwimmer has been promoted to the chair of Dermatology.

Clausenburg.—Dr. Udransky of Buda-Pesth has been appointed to an Extraordinary Professorship of Physiology.

Gratz.—Dr. A. Elschnigg has been recognised as *privat-docent* in Ophthalmology.

Madrid.—Senor D. Dr. A. Redondo y Carranceja, Professor of Clinical Medicine in the Valladolid School, has been appointed to the chair of Medical Pathology.

Marburg.—Dr. F. Müller of Breslau has been appointed to the chair of Medicine.

Philadelphia (Jefferson College).—Dr. E. Montgomery has been appointed Professor of Clinical Gynæcology; Dr. F. X. Dercum, Professor of Nervous Diseases; Dr. E. Graham, Professor of Children's Diseases; Dr. H. W. Stelwagon, Professor of Dermatology; and Dr. W. M. Coplin, Assistant Professor of Hygiene.

Sienna.—Dr. Gius Sanarelli has been recognised as *privat docent* in Hygiene.

St. Petersburg (Military Medical Academy).—The number of candidates for the vacant chair of special pathology and therapeutics is very large, and includes Professor Dobroklonski of Warsaw, Professor Kurloff of Tomsk, Dr. Dokhman of Kazan, and a number of the present lecturers in the Academy.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Carl E. Lenz, consulting member of the Russian Medical Council at the age of seventy-one. He had travelled much and had lived for some time in Alaska. He was Russian delegate to the Cholera Conferences in Constantinople in 1865, and in Vienna in 1874. Amongst his literary works was an important abstract in Russian of Hirsch's Pathological History and Geography.—Dr. Ludwig Marovski, of Odessa, formerly professor in Kharkoff.

THE Select Committee of the House of Lords on the Metropolitan Hospitals resumed their work at Westminster on Thursday. The members present were Lord Sandhurst, Earl Cadogan, the Earl of Kimberley, the Earl of Arran, Earl Cathcart, Lord Thring, Lord Clifford of Chudleigh, and Lord Zouche of Haryngworth. As a matter of form, Lord Sandhurst was reappointed chairman of the committee The special purpose of the meeting was to hear evidence with regard to a uniform system of hospital accounts, but the expected witness did not attend, and their lordships employed the time considering their draft report.

AS Emeritus Professor of Clinical Surgery, Mr. Hutchinson, F.R.S., will deliver a course of six lectures on Thursdays, at 4 o'clock, in the clinical theatre at the London Hospital, commencing on Thursday, May 12th: (1) On Melanosis, May 12th; (2) on Operations for Cancer, May 19th; (3) on Different Forms of Chancre, May 26th; (4) on the Old and the Modern Treatment of Syphilis, June 2nd; (5) on the Nature of Eczema, June 9th; (6) on Arsenic, Mercury, and Opium, June 16th. Members of the profession will be admitted on presentation of their address cards.

A REUTER'S telegram from Cairo states: "Dr. Milton, chief medical officer of the native hospital here, is about to bring an action for libel against the newspaper *Le Bosphore*, on account of a violent article recently published in that journal attacking the English doctors practising here, and containing allegations regarding them which are alleged to be altogether unjust. Dr. Milton claims substantial damages."

DR. HOLMAN, the treasurer of the Royal Medical Benevolent College, will be presented with a testimonial on the occasion of his relinquishing practice at Reigate on Saturday, 14th inst., at 6.30 P.M., in the old Town-hall.

Digitized by Google

SIR WILLIAM ROBERTS, M.D., F.R.S., will deliver the Croonian Lectures, on the Chemistry and Therapeutics of Uric-acid Gravel and Gout, at the Royal College of Physicians, Pall Mall East, on June 14th, 16th, 21st, and 23rd, at 5 P.M.

THE next triennial prize of £300 under the will of the late Sir Astley P. Cooper, Bart., will be awarded for the best essay or treatise on the Anatomical Distribution of the Lymphatic Vessels and the Physical Forces concerned in the Movement of the Lymph.

THE annual dinner of old students of King's College, will be held on Monday, May 30th next, at the Freemasons' Tavern, Great Queen-street, Long Acre, when Dr. W. O. Priestley, of King's College Hospital, will preside.

BY the desire of the Prince and Princess of Wales, the addition to the St. Mary's Hospital, Paddington, is to be called the Clarence Memorial Wing.

THE half-yearly dinner of the Aberdeen University Club will take place at the Holborn Restaurant on Wednesday, May 18th.

A COURSE of lectures, free to practitioners and senior students, has been commenced at the National Orthopædic Hospital.

FIFTH REPORT OF THE ROYAL VACCINATION COMMISSION.

THE following is the text of the interim report which has been issued by the Royal Commissioners on Vaccination:—

We, the undersigned Commissioners appointed to inquire into the subject of vaccination, desire humbly to submit to your Majesty a further report of our proceedings.

In the first report which we submitted to your Majesty we stated that, considering it would contribute to clearness if the evidence on the several points submitted to us were kept distinct, we had decided to take evidence upon those questions as far as practicable in the following order:—

1. The historical and statistical case in favour of vaccination.
2. The arrangements made for vaccination under the existing law, and the mode in which the law is administered.
3. The case against vaccination, and especially against its continuing to be made compulsory.
4. The reply to these objections.
5. Any substitutes that can be suggested in place of vaccination for the purpose of preventing the spread of small-pox.
6. Any improvements that can be suggested in the present law or its administration for the purpose of removing objections to vaccination or making it more effective.

We have held ninety meetings and examined one hundred and thirty-five witnesses. The evidence we have taken hitherto has been mainly directed to the first three subdivisions of our inquiry, but we have not yet completed the evidence bearing upon any of them. It is obvious, therefore, that we are not in a position to express any opinion upon the main questions submitted to us for inquiry and report. But it has been suggested that, though unable to pronounce an opinion upon those questions, it might be in our power, without prejudice to the inquiry which is still in progress, to make recommendations with reference to certain subsidiary questions to which our attention has been called.

Having carefully considered this suggestion, we have come to the conclusion that we may properly make recommendations upon certain points to which we will now advert.

"Under the existing law every parent or person having the custody of a child who, without having reasonable excuse, neglects to take it to be vaccinated is rendered liable, on conviction, to a penalty not exceeding 20*s*. In addition to this, where the vaccination officer gives information to a justice of the peace that he has reason to believe that a child under fourteen years of age has not been successfully vaccinated, and that he has given notice to the parent or person having the custody of such child to procure its being vaccinated, and that this notice has been disregarded, the justice may make an order directing the child to be vaccinated within a certain time, and, if the order be not complied with, and no sufficient ground shown for non-compliance, the person on whom such order has been made is rendered liable to a penalty not exceeding 20*s*. And this enactment has been held by the Courts to warrant repeated orders in respect of the non-vaccination of a child, and the imposition of a penalty for the disobedience of each of such orders, notwithstanding that previous penalties have been inflicted.

"We think that the imposition of repeated penalties in respect of the non-vaccination of the same child should no longer be possible. In the year 1875 the Local Government Board wrote a letter to the guardians of Evesham Union, which was afterwards sent to many other boards of guardians and made public, pointing out that by Article 16 of the Board's General Order, 1874, it was provided that in any case in which a magistrate's order had been obtained and summary proceedings taken under Section 31 of the Vaccination Act, 1867, no further proceedings should be taken by the vaccination officer without the express instructions of the guardians. The letter further stated that the intention of this provision was that the guardians should carefully consider with regard to each individual case the effect which the continuance of the proceedings would be likely to have in promoting the vaccination of the individual child and in insuring the observance of the law in the union generally. Although the publication of this letter has, no doubt, had considerable effect in diminishing the number of cases in which repeated penalties have been inflicted, it has by no means put an end to them. We think that they should cease to be inflicted altogether. We have arrived at this conclusion quite independently of the question whether vaccination should continue to be compulsorily enforced. Whatever be the conclusion which we may have to submit to your Majesty upon this part of our inquiry, and even if it should ultimately appear that we are not able all to agree in the same conclusion, we have had no difficulty in agreeing upon the recommendation which we now submit.

"It is unnecessary to state at any length our reasons for the recommendation. Those who favour the view that vaccination ought not to be compulsory are naturally opposed to repeated convictions in respect of the failure to vaccinate a particular child, whilst those who incline to the opposite view believe that any advantage which may arise from the tendency of repeated convictions to increase the number of the vaccinated is more than counterbalanced by the resentment and active opposition to vaccination which they engender.

"Our attention has been directed to the treatment to which persons are subjected who have been committed to prison by reason of the non-payment of penalties imposed under the vaccination laws. It appears that in the case of one person so committed he was shortly after his commitment removed to the debtors' ward. The governor, apparently entertaining a doubt as to the mode in which the prisoner should be treated, applied to the Home Office for instructions. In reply to this application instructions were given 'that he should be treated as a simple imprisoned prisoner—that is to say, as a convicted criminal prisoner not sentenced to hard labour.' He was accordingly removed from the debtors' ward and returned to a cell, and received for the remainder of the term the treatment indicated in the instructions from the Home Office. The 38th section of the Prisons Act, 1877, empowers the Secretary of State to make rules with respect to the classification of prisoners imprisoned for non-compliance with the order of a justice or justices to pay a sum of money, or imprisoned in respect of the default of a distress to supply the sum of money adjudged to be paid by order of a justice or justices, so that such rules are in mitigation and not in increase of the effect of such imprisonment as regulated by the Prisons Act, 1865. We understand from answers given in Parliament that the Secretary of State for the Home Department is of opinion that this section does not enable him to provide that persons imprisoned under the Vaccination Act should not be subjected to the same treatment as criminals. We do not con-

Digitized by Google

sider that it is within our province to express any opinion upon this point, but we have no hesitation in saying that we think the power ought both to exist and to be exercised, and that persons imprisoned under the Vaccination Act should no longer be subjected to the same treatment as criminals. Many of those whose imprisonment arises from their contravention of the laws relating to vaccination regard the practice as likely to be injurious to the health of their children, and are well-conducted and in other respects law-abiding citizens. Even those who consider that the course which such persons adopt is a mistaken one may nevertheless still be of opinion that they ought not during their imprisonment to be subjected to the treatment awarded to criminals, such a proceeding not being calculated to secure obedience to the law or to add to the number of vaccinated."

THE UNIVERSITY OF LONDON.

THE usual meeting of Convocation was held on Tuesday at 5 P.M., at the University Building in Burlington-gardens. Mr. E. H. Busk, M.A., LL.B., was the only graduate nominated as chairman in succession to the late Dr. Wood, and was elected. The names of three persons were then voted for, who should be submitted to Her Majesty for the selection therefrom of a Fellow of the University. Mr. E. H. Busk obtained 781 votes, Mr. W. G. Lemon 143, and Mr. Talfourd Ely 136.

Dr. Napier presented the report of the annual committee, and with Dr. Baines moved a vote of sympathy with the family of the late Dr. Wood. Dr. W. J. Collins moved the next resolution as follows: "That the annual committee be requested to represent the views and guard the interests of Convocation generally in all matters connected with the proposed Royal Commission, and any scheme which may be submitted to it, and that for this purpose they be empowered to confer and to take joint action with the Senate, and to act otherwise as may seem expedient."

Sir Albert Rollit preferred a special committee; but, after some discussion, the original proposal was carried. The advisability of instituting degrees in languages was again referred to the annual committee.

Dr. O'Reilly moved for precedence for the following resolution, which was carried, and copies are to be forwarded to the First Lord of the Treasury, the Home Secretary, and the Member of Parliament for the University: "That this House learns with surprise and regret that the new Royal Commission on a Teaching University for London includes no member who can be regarded as representative of the Convocation of the London University, a body consisting of more than 3000 graduates deeply interested in the future of University education in the metropolis."

Mr. Sully and Mrs. Bryant, D.Sc., urged the institution of a high degree in connexion with the scientific study of education, but this was lost by the casting vote of the chairman. The annual committee were balloted for, and the House was shortly afterwards counted out.

The proceedings on the presentation day were of the usual character. Lord Derby made a graceful chairman, and was most complimentary in his felicitations to the graduates and undergraduates who were presented for their medals and certificates.

LONDON COUNTY COUNCIL.

THE Chairman of the Public Health Committee of the London County Council has issued a memorandum in explanation of the amendment required in the law to prevent the future erection of domestic dwellings in London, whether on new foundations or in substitution for old buildings, except in accordance with regulations securing an adequate amount of open space both in front and rear. The object of the memorandum is to indicate (1) the existing law on the subject as affecting domestic buildings in London; (2) the law as affecting those in the provinces and the manner in which effect has been given to it; (3) the amendment of the law required for London. Dealing with the third head the memorandum states that:—

The Royal Commissioners on the Housing of the Working Classes, in their report of 1885, dealt with the subject. The Commissioners, after stating that no attempt had hitherto been made to control the height of buildings in the metropolis in relation to the open space provided, and giving it as their opinion that the existing regulations as to such open space were not sufficient or satisfactory, made the following recommendations, subject to limitations which might be found necessary to prevent undue sacrifice of property in individual cases:—1. That upon the lines of the existing enactments in the Acts of 1862 and 1878, rules of more general application be framed to control the height of buildings in relation to the open space which should be required to be provided in front of the buildings, either in the form of land exclusively belonging to each building and kept free from erections, in the form of an adjoining street. 2. That in the rear of every new dwelling house or other building, and whether in old or in new streets, there be provided a proportionate extent of space exclusively belonging to the dwelling house or building; that this space be free from erections from the ground level upwards; that it extend laterally throughout the entire width of the dwelling house or building; that for the distance across the space from the building to the boundary of adjoining premises a minimum be prescribed; and that this minimum increase with the height of the dwelling house of building. As will be observed, the model by-laws proceed upon the lines of both these recommendations with regard to buildings outside London. The long-wished-for opportunity of amending the law with regard to the Metropolis is now offered by the pending consolidation of the Building Acts.

The late Building Act Committee suggested that the amendment should be effected by the adoption of much the same rule as that adopted by Liverpool, so far as the space in rear of dwellings is concerned, leaving untouched the question of the open space in front, but with the proviso that every owner of an existing house should have reserved to him the full right to rebuild his house on the old foundations, provided the dimensions are not altered. If an amendment of the law goes no further than this, it will hardly effect much; 18 feet streets will still remain 18 feet streets, and it will still be possible for houses fronting on them to be erected up to 90 feet. That to give full effect to both the recommendations of the Royal Commissioners must mean a sacrifice of property, and of very valuable property too, is of course evident; but land in the heart of Manchester and Liverpool is probably as valuable as land in the congested districts of London, and if the sacrifice is called for in those cities, it is surely equally called for in London; moreover, the principle of calling upon owners of house property in certain circumstances to make sacrifices for the general welfare of the community is admitted—e.g., the compulsory setting back on taking down and rebuilding to the general line of buildings when such has been once fixed, which setting back has to be done without compensation, that cases of exceptional hardship would inevitably arise if the Liverpool rules were applied to London goes without saying; for example, where a house is pulled down and the building site is of insufficient extent to allow of any rebuilding in face of the new regulation; but that is not sufficient excuse for longer delaying the only possible remedy against the evils, which, bad as they are now, may become far worse as the sanitary authorities and the Council enforce the Housing and Public Health Acts by insisting on the closing and demolition of insanitary houses, and even if compensation in individual cases should be unavoidable, this would be a cheaper arrangement for the ratepayers than the extravagant clearance schemes which must otherwise be continuously undertaken if London is to be a healthy city. Assuming the principles involved in the model by-laws to be applicable to London, it would doubtless be desirable in calculating the open space in front of new houses that the measure should be taken from the centre of the street, and that the provision so far should apply to all classes of buildings, and not be confined to domestic ones; but what the distance across should be, and whether the provision as to space in the rear is sufficient to put a reasonable limit on the actual height of the house itself, are matters which require to be considered by experts. Meanwhile the most reasonable suggestion which could be put forward at the present juncture would probably be the introduction of a clause in the proposed amendment Bill giving similar power to the Council to make by laws dealing with the matter, subject to confirmation by the Local Government Board, to that possessed by urban authorities outside London.

April 30th, 1892. R. MELVILL BEACHCROFT.

THE BELFAST LUNATIC ASYLUM BILL.

THIS Bill has been before a Select Committee of the House of Commons, consisting of the Right Hon. G. J. Shaw-Lefevre, Mr. A. Elliot, Sir Edward Harland, Mr. Hinckes, Mr. Knox, Mr. Sexton, and Mr. T. W. Russell, on Mondays and Thursdays during the past three weeks. The existing Belfast lunacy district includes Belfast city, with a population of 260,000, and the county of Antrim, which, excluding Belfast, has a population of nearly 200,000. In the whole district there are about 250 idiots and imbeciles, and 1200 other insane persons, who for practical purposes are regarded as pauper lunatics. The only available asylum accommodation hitherto provided for this large and afflicted class has been the Belfast Asylum, which nominally accommodates 550 patients, and which for some time past has been so overcrowded that in at least one division the patients are obliged to sleep in the corridors. In addition to the patients

Digitized by Google

actually inhabiting the asylum, 100 lunatics have been transferred thence to Ballymena Workhouse under the provisions of Sec. 9, 38 and 39 Vict., cap. 67, the names of the lunatics continuing on the asylum books, and the governors still receiving the treasury capitation grant of 4s. a week towards their maintenance. The remaining 800 lunatics and idiots are scattered at large throughout the district or are located in the different workhouses, where they are detained without legal sanction, and where their condition and treatment are generally extremely unsatisfactory. It is now proposed that the present Belfast Asylum should be devoted exclusively to city patients, and that a new, and in every respect modern asylum, should be erected for the county patients at Holywell, close to the town of Antrim, where a beautiful site overlooking Lough Neagh has been acquired for the purpose by the board of control. It was found, however, that this scheme could not be carried out without legislation, inasmuch as Belfast, although the city of a county by charter, has no separate taxing and presenting powers, and that therefore the Lord Lieutenant had no power to separate it from the rest of the county of Antrim and constitute it a separate lunacy district. The Bill conferring on the corporation of Belfast the financial powers to maintain a city asylum is opposed by certain of the Roman Catholic inhabitants of Belfast, on the grounds that the change proposed would be injurious to the ratepayers, and that no fresh or further powers should be conferred on the corporation until the city has been divided into a larger number of wards than five, so that the Roman Catholic minority might have some chance of obtaining representation on the city council. The Parliamentary Committee has taken a large amount of evidence, and has examined among others Dr. Alex. Merrick, the resident medical superintendent of Belfast Asylum, and Dr. Plunkett O'Farrell, one of Her Majesty's inspectors of lunatics and a commissioner of control for the erection of lunatic asylums in Ireland. The opponents of the Bill admit the necessity for further lunacy accommodation, but they contend (1) that it would be better and cheaper to have only one board of visitors for the management of the two asylums, and (2) that it would be desirable to be able to classify the patients between the city and county asylums; and the medical evidence has been chiefly directed to these two points. The principle of having a single board of visitors or governors for two distinct institutions is not in the abstract desirable, and in the particular instance of Belfast is certainly objectionable. The single board of visitors would be composed of somewhat irreconcilable elements; the town members would come into occasional conflict with the country members. The two institutions would differ in many ways, each would have its special wants and perhaps its special faults; but the members of the single boards, some of whom would be more interested in one asylum than the other, would not be impartial judges. Moreover, the delicate question of proportionate representation would have to be approached, and the giving of a majority to one or other element would be certainly resented.

In England it has been found absolutely essential to manage each lunatic asylum by its own subcommittee, or board of visitors, and comparatively small towns like Ipswich, Derby, Exeter, Portsmouth, &c., have now their own small "borough" asylums, and have no relations with the large county asylums. As regards the second point, the attempt to classify patients by their chances of recovery has failed everywhere it has been tried. When the third Middlesex asylum was built at Banstead it was intended that it should provide only for chronic and so-called "incurable" cases. It was very soon found impossible to maintain or work this plan, and so it was abandoned, and no attempt has been made to repeat the experiment. On the contrary, the great new asylum at Claybury is being specially erected for the accommodation of both classes, "curable" and "incurable." In Germany a few generations ago it was a favourite idea to divide asylums into "cure institutions" (Heil-Anstalten) and "care institutions" (Pflege-Anstalten). But practically it was found that this system would not work, and the majority of the asylums are now "cure and care institutions" (Heil- und Pflege-Anstalten).

It is no doubt occasionally desirable, on medical grounds, to transfer borough or city patients to the country. This advantage could be gained by a friendly arrangement between the two boards of visitors of the Belfast and the new Antrim Asylum, or by the far better plan, now adopted by nearly all the English lunacy hospitals, of building a small seaside convalescent asylum for the city patients, where no doubt they would have a far better chance of recovering and regaining mental stability than in the best-managed county or district asylum.

THE GENERAL PRACTITIONERS' ALLIANCE.

THE General Practitioners' Alliance having represented to the Privy Council the desirability of appointing representatives of the medical profession not connected with the governing bodies of existing corporations to serve on the Royal Commission appointed to inquire into the subject of the Gresham University, a reply to the following effect has been received. The Lord President, in the communication, states that "it is quite impossible for his lordship to receive deputations upon the composition of the Royal Commission. The names have been submitted to, and approved of by, Her Majesty, and the numbers are already large, medicine being strongly represented. Evidence can, of course, be given upon any special points, and the members of the Commission, other than the medical members, can judge of the value of the evidence and give effect to it. The Lord President regrets that he is unable to accede to the resolution of the General Practitioners' Alliance, as other bodies who have sought for additions to the Royal Commission would claim to be heard in person."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6718 births and 3841 deaths were registered during the week ending May 7th. The annual rate of mortality in these towns, which had been 21·8 and 20·8 per 1000 in the preceding two weeks, further declined last week to 19·7. In London the rate was 18·9 per 1000, while it averaged 20·2 in the thirty-two provincial towns. The lowest rates in these towns were 14·3 in Halifax, 14·9 in Cardiff, 15·7 in Norwich and in Huddersfield, and 15·0 in Nottingham; the highest rates were 23·9 in Preston, 24·1 in Oldham, 24·2 in Liverpool, and 28·3 in Sunderland. The 3841 deaths included 541 which were referred to the principal zymotic diseases, against 541 and 527 in the preceding two weeks; of these, 237 resulted from measles, 152 from whooping-cough, 43 from diphtheria, 42 from scarlet fever, 41 from diarrhœa, 25 from "fever" (principally enteric), and 1 from small-pox. No fatal case of any of these diseases occurred last week in Norwich; in the other towns they caused the lowest rates in Hull, Nottingham, Derby, and Birkenhead, and the highest rates in Sheffield, Salford, Leicester, and Sunderland. The greatest mortality from measles occurred in Birmingham, Sunderland, Liverpool, London, Leicester, and Sheffield; from whooping-cough in Manchester, Croydon, Bristol, Bolton, and Sunderland; and from diarrhœa in Salford and Preston. The mortality from scarlet fever and from "fever" showed no marked excess in any of the thirty-three large towns. The 43 deaths from diphtheria included 31 in London, 4 in Manchester, and 2 in Salford. One fatal case of small-pox was registered in London, but not one in any of the thirty-two provincial towns; 47 cases of this disease were under treatment in the Metropolitan Asylum Hospitals, and 12 in the Highgate Small-pox Hospital, on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1484, against 1400 and 1408 on the preceding two Saturdays; 200 new cases were admitted during the week, against 219 and 177 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 389 and 306 in the preceding two weeks, further declined to 297 last week, and were 61 below the corrected average. The causes of 72, or 1·9 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Croydon, Portsmouth, Norwich,

Digitized by Google

Bolton, Hull, and in eight other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Blackburn, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined from 24·1 to 21·3 per 1000 in the preceding four weeks, was 21·4 during the week ending May 7th, and exceeded by 1·7 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 17·1 in Leith and 17·3 in Edinburgh to 23·7 in Glasgow and 28·9 in Greenock. The 596 deaths in these towns included 30 which were referred to whooping-cough, 22 to measles, 5 to scarlet fever, 4 to diarrhœa, 3 to "fever," 1 to diphtheria, and not one to small-pox. In all, 65 deaths resulted from these principal zymotic diseases, against 63 and 70 in the preceding two weeks. These 65 deaths were equal to an annual rate of 2·3 per 1000, which was 0·5 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 22 and 26 in the preceding two weeks, further rose last week to 30, of which 24 occurred in Glasgow and 2 each in Edinburgh, Dundee, and Aberdeen. The deaths referred to measles, which had been 15 and 18 in the previous two weeks, further increased to 22 last week, of which 21 were recorded in Glasgow. The 5 fatal cases of scarlet fever also showed a slight further increase upon recent weekly numbers, and included 3 in Glasgow. The 4 deaths from diarrhœa were considerably below those recorded in any recent week, and the fatality of diphtheria and of "fever" also showed a decline. The deaths referred to diseases of the respiratory organs in these towns, which had been 163 and 139 in the preceding two weeks, further declined last week to 126, and were 31 below the number in the corresponding week of last year. The causes of 58, or nearly 10 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased in the preceding three weeks from 30·6 and 43·9 per 1000, declined again to 33·0 during the week ending May 7th. During the first five weeks of the current quarter the death-rate in the city averaged 35·3 per 1000, the rate for the same period being 20·3 in London and 19·5 in Edinburgh. The 221 deaths in Dublin during the week under notice showed a decline of 73 from the exceptionally high number in the preceding week, and included 40 which were referred to measles, 4 to whooping-cough, 2 to diarrhœa, 1 to diphtheria, and not one either to small-pox, scarlet fever, or "fever." In all, 47 deaths resulted from these principal zymotic diseases, equal to an annual rate of 7·0 per 1000, the zymotic death-rate during the same period being only 3·6 in London and 2·8 in Edinburgh. The fatal cases of measles, which had been 33 and 20 in the preceding two weeks, rose again to 40 last week, and exceeded the number recorded within the city in any week since January, 1882. The deaths referred to whooping-cough, which had increased in the previous three weeks from 5 to 11, declined again to 4 last week. The 221 deaths registered in Dublin last week included 39 of infants under one year of age, and 37 of persons aged upwards of sixty years; the deaths of infants showed an increase, while those of elderly persons were considerably below those recorded in any recent week. Three inquest cases and 5 deaths from violence were registered; and 65, or nearly one-third, of the deaths occurred in public institutions. The causes of 20, or more than 9 per cent., of the deaths in the city last week were not certified.

CALCUTTA VITAL STATISTICS.

We learn from the report of Dr. W. J. Simpson, health officer for Calcutta, on the vital statistics of that city and its amalgamated area of suburbs, that the total number of births registered in Calcutta in January last was 787, in the annual ratio of 20·2 per 1000 of population. Of the 787 births, 405 were males and 382 females. The decennial mean was 683. The total number of deaths, exclusive of still-births, registered in January was 1302, against 1380 in the preceding month, showing an annual ratio of 33·4, against 35·5 per 1000. The proportion of male to female deaths was as 140 to 100. The monthly total exceeds all the corresponding figures of the past decade, excepting 1883, and also exceeds the decennial mean by 137. There were 57 deaths from cholera, against 98 in the preceding month. The number is less than all the corresponding figures for the last ten years, excepting 1884, and is also less than the average of the decade. There was only one death from small-pox registered during the month. The deaths from fevers amounted to 497, against 536 in the previous month. The total exceeds all the corresponding numbers for the past ten years, and also surpasses the decennial mean by 154. Tetanus among infants reached, as usual, a high figure. There were 46 deaths from tetanus, against 47 in the previous month. Of these, 39 were under one year of age. The mortality of infants under one year of age, reckoned on estimated births, was 287·2, against 306·0 in the preceding month per 1000 of population per annum. In the amalgamated area of the suburbs there were 404 births registered in January, giving an annual ratio of 22·5 per 1000. Of these, 223 were male births and 181 female. The total number of deaths registered in January was 828, in the annual ratio of 46·1 per 1000 of population. Of these deaths there were 35 from cholera, 346 from fevers, 148 from bowel complaints, 46 from tetanus, 6 from injuries, and 247 from other causes.

THE SERVICES.

THE REPORT OF LORD WANTAGE'S COMMITTEE.

THE absence of Mr. Stanhope from the House of Commons owing to ill-health will, in all probability, interpose an obstacle to the intended debate on the recommendations of Lord Wantage's Committee on the terms and conditions of service in the Army. This is to be regretted, for the subject is one which needs threshing out in the House of Commons; but neither the Government nor the opposition will, we fancy, be sorry to escape declaring their future action in difficult matters involving an increased expenditure amounting altogether to some two millions a year. Sooner or later the subject must, however, be taken in hand. The soldier regards the present system of compulsory stoppages, not due to negligence or misconduct on his part, as a great grievance. He thinks their imposition opposed to the representations made to him on enlistment, and considers that he should be housed, clothed, and fed at the cost of the State, and able to count on some fixed sum in the way of daily pay to spend as he likes—not a very unreasonable way of looking at it!

DISTINGUISHED TRAVELLERS.

Two officers, one of whom is a medical officer, have recently accomplished a feat in the way of travelling which speaks well for their enterprising spirit and powers of endurance. It is stated by a correspondent that Captain Bower, of the 17th Bengal Cavalry, and Surgeon Thorold, of the Indian Medical Service, had passed through Shanghai. The names of these officers will, we believe, be added to the list of distinguished British travellers. They journeyed through Thibet by the longest route that can be taken through that country. They passed from the Cashmere frontier in the north-west to the Chinese province of Szechuen, which adjoins the south-eastern border of the territories of the Delai Lama. They spent upwards of ten months in Thibet, and a great part of their journey lay through a series of elevated table lands, seldom lower than 15,000 feet above the sea level. No foreign travellers have, it is alleged, previously followed the same route, and we may consequently look forward to an interesting record of their experiences.

THE LATE RISING IN NORTH LUSHAI.

We learn that the medical officer whose exhibition of bravery and coolness, under trying circumstances, in connexion with the late expedition in North Lushai land, was mentioned in the reports of the campaign, is not Surgeon-Captain C. H. Melville, of the Army Medical Staff, but Surgeon-Captain Henry Bruce Melville, of the Indian Medical Service, who is stationed at Fort Aijal, North Lushai, in medical charge of the frontier police, and is Civil Surgeon of the Lushai Hills.

Digitized by Google

INDIAN MEDICAL SERVICE.

It was announced that Surgeon-Major Coates, the Junior Civil Surgeon at Simla, had been appointed Civil Surgeon at Lahore, Surgeon Cunningham succeeding him; but according to the latest arrangement it appears that Surgeon-Major Coates will remain at Simla, and not go to Lahore as stated.

Surgeon-Major C. F. Willis, I.M.S., 9th Bombay Infantry, who has been officiating in medical charge of the 21st Bombay Infantry during the absence of Surgeon-Major Burroughs, I.M.S., departed for Mhow on the 13th ult., to rejoin his regiment, on the arrival of the latter officer from leave in England.

Surgeon-Captain A. Street, I.M.S., on general duty, Poona, has been appointed to officiate in medical charge, 26th Regiment Bombay Infantry, vice Surgeon-Captain H. Herbert, I.M.S., transferred to the Civil Department.

The services of Surgeon-Captain H. Herbert, F.R.C.S., I.M.S., have been placed at the disposal of Government for employment in the Civil Department.

Surgeon-Captain Baman Das Basu has been appointed to act as Civil Surgeon, Jacobabad, with effect from the 22nd ult., in addition to his other duties.

Surgeon-Captain J. Crimmin, V.C., I.M.S., has been appointed to act as Port Surgeon, Aden, during the absence of Surgeon-Major C. Monks, I.M.S., or until further orders; Surgeon-Captain A. F. Cleveland, I.M.S., holding charge, pending the arrival of Surgeon-Captain Crimmin.

Surgeon-Captain H. Herbert, F.R.C.S., I.M.S., acts as Second Surgeon, Jamsetjee Jejeebhoy Hospital, during the deputation of Surgeon-Major W. K. Hasch, to act as Senior Medical Officer in charge, Jamsetjee Jejeebhoy Hospital, and Senior Surgeon, Jamsetjee Jejeebhoy Hospital.

Surgeon-Major Robertson and his party of frontier tribesmen have passed through Lahore on their way home. They had been a little depressed by the sudden death from cholera of the Assistant Medical Officer to the party.

Surgeon-Lieutenant-Colonel H. J. Linton, I.M.S. (26th P.N.I.), died at Peshawur on the 4th ult. He joined the Indian Medical Service in 1869, served in the Afghan War of 1878–80, and took part in the second expedition into Bazar Valley and in the advance to the relief of Cabul under Brigade-General C. Gough (mentioned in despatches); accompanied Sir Frederick Roberts in the march to Candahar, and was present at the battle of Candahar (mentioned in despatches, medal with two clasps and bronze decoration).

ARMY MEDICAL STAFF.—Surgeon-Major F. W. Trevor and Surgeon-Captain C. J. W. Tatham have been ordered to Woolwich for duty. — Brigade-Surgeon-Lieutenant-Colonel J. B. Kelly, in medical charge of the Station Hospital at Belgaum, has been appointed to the medical charge of South Station Hospital, Bangalore. — Surgeon-Lieutenant-Colonel A. L. Brown, in charge of South Station Hospital, Bangalore, has been transferred to the charge of the Station Hospital at Belgaum.—Surgeon-Captain W. J. Crofton has been placed on temporary half-pay on account of ill-health.—Surgeon-Colonel Wm. Collis to be Surgeon-Major-General, vice A. M. Tippetts (retired), Brigade-Surgeon-Lieutenant-Colonel Francis Henry Welch, F.R.C.S. Eng., to be Surgeon-Colonel, vice W. Collis, and Surgeon-Lieutenant-Colonel Henry Comerford, M.D., to be Brigade-Surgeon-Lieutenant-Colonel, vice F. H. Welch (all dated April 5th, 1892).

ARMY MEDICAL RESERVE OF OFFICERS. — Surgeon-Lieutenant Colonel William Warman Coleman, having resigned his Volunteer appointment, ceases to be an Officer of the Army Medical Reserve of Officers (dated May 11th, 1892).

MILITIA MEDICAL STAFF.—Surgeon-Lieutenant-Colonel R. J. Magee, 5th Battalion, the Royal Irish Regiment, whose resignation was notified in the *London Gazette* of Feb. 26th, is permitted to retain his rank, and to wear the prescribed uniform on his retirement (dated Feb. 27th, 1892).

YEOMANRY CAVALRY. — Royal Wiltshire (Prince of Wales's Own Royal Regiment): Geo. Thelwall Kindersley Maurice, Gent., to be Surgeon-Lieutenant (extra), under paragraph 33 (*a*) Yeomanry Cavalry Regulations, 1889 (dated May 9th, 1892).

NAVAL MEDICAL SERVICE.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Inspector-General of Hospitals and Fleets Doyle Money Shaw, C.B., has been placed on the Retired List of his rank at his own request (dated April 27th, 1892).—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Inspector-General of Hospitals and Fleets John Fisher has been placed on the Retired List at his own request. Surgeon and Agent: John G. Wilson, M.B., at Porlock and Minehead (dated May 11th, 1892).

VOLUNTEER CORPS.—*Artillery:* 1st Aberdeenshire: Surgeon-Major J. Rodger, M.D., to be Surgeon-Lieutenant-Colonel (dated May 11th, 1892). — *Rifle:* 4th Volunteer Battalion, the Cheshire Regiment: Surgeon-Captain W. Bale to be Surgeon-Major, to resign his commission, to be granted permission to retain his rank, and to continue to wear the uniform of the battalion on his retirement; and Hyde Marriott, M.B., to be Surgeon-Lieutenant (both dated May 11th, 1892).—1st (City of Bristol) Volunteer Battalion, the Gloucestershire Regiment: Surgeon-Lieutenant A. W. Prichard to be Surgeon-Captain (dated May 11th, 1892).—1st Volunteer Battalion, the East Lancashire Regiment: Surgeon-Lieutenant W. Wallers resigns his commission (dated May 11th, 1892)—1st Volunteer Battalion, the Manchester Regiment: William Fitzwilliam O'Grady, Gent., to be Surgeon-Lieutenant (dated May 11th, 1892).

"Audi alteram partem."

THE OATH OF HIPPOCRATES.

To the Editors of THE LANCET.

SIRS,—The authority of THE LANCET is deservedly so great on all matters pertaining to the history, theory, and practice of medicine, that its opinion may generally be accepted without scrutiny or challenge. Nevertheless, I venture to think that one of the inferences it draws from the Hippocratic Oath is not, historically or logically, well founded.

In an interesting annotation entitled "The Oath of Hippocrates," it is stated: "An expressed objection to the performance of lithotomy affords an early sign of the deepening cleavage between the provinces of the physician and the surgeon" (p. 1039). The Hippocratic phrase, "I will not cut any one suffering from stone" (*οὐ τεμέω δὲ οὐδὲ μὴν λιθιῶντας*), has confessedly puzzled and perplexed most commentators, and many conjectures have been hazarded as to what it does mean, and many hypothetical emendations of the text have been proposed in order to make the meaning clearer or more intelligible. It is no part of my present purpose to discuss these conjectures and emendations or to attempt any elucidation of the text. I merely submit that, whether it was intended to proscribe the operation of cutting for vesical calculus or not, or whether some other operation was referred to (e.g., castration as some suppose) the interdiction does not afford any evidence of a "cleavage between the provinces of the physician and the surgeon." Respecting this particular assumption, Littré emphatically declares "une pareille opinion ne peut soutenir le moindre examen,"[1] and he observes that the Hippocratists performed all kinds of operations, severe as well as slight.

The context, and indeed the whole tenour of the Oath, shows that whatever may have been the grounds for proscribing this operation, they were of an ethical or *moral* nature, and not purely *technical*. There is nothing in the Hippocratic writings, or in the works of the other ancient Greek and Roman medical authors, to indicate why this operation of cutting for stone was specially and *exclusively* prohibited. No other operation in surgery is proscribed; all the other procedures mentioned in the Oath only to be condemned are obviously criminal or offensive and immoral.

I am, Sirs, yours faithfully,

Harley-street, W., May 10th, 1892. JOHN TWEEDY.

PRESENTATION TO SIR GEORGE BUCHANAN, F.R.S.

To the Editors of THE LANCET.

SIRS,—As you are doubtless aware Sir George Buchanan has lately resigned the post of Medical Officer to the Local Government Board. A committee has been formed with a view to forwarding a movement for enabling those interested in public health throughout the country to give expression to the high estimation in which they hold the important work which Sir George Buchanan has done, and for affording some opportunity for the recognition of his conspicuous services in the cause of preventive medicine. Under these circumstances it has been decided to open a subscription list (not to exceed two guineas from each contributor) with a view to presenting to Sir George Buchanan some permanent memento of the esteem in which he and his work are held. The Council of the Society of Medical Officers of Health has expressed a desire to be associated with the committee in inviting subscriptions to the fund.

We are, Sirs, faithfully yours,

J. S. BRISTOWE, Hon. Treasurer.
W. H. HAMER,[1] Ladywell, 69, Dartmouth-park-hill, N.W. } Hon. Secs.
J. C. THRESH,[1] The Limes, Chelmsford, Essex. } Hon. Secs.

COMMITTEE.—Sir Henry Acland Bart., K.C.B., M.D., F.R.S., Chairman; Dr. Bristowe, F.R.S., Treasurer; Sir Anthony Home, Bart., K.C.B., V.C., M.D.; Dr. Tatham, Dr. Henry Armstrong; Dr. Whitelegge; Dr. Maccabe; Sir William Jenner, Bart.; Sir George Humphry; Dr. Thorne Thorne, F.R.S.; Sir Joseph Fayrer; Dr. B. W. Richardson; Dr. Marcet; Shirley F. Murphy, Esq., President;* S. R. Lovett, Esq., Hon. Treasurer;* A. Wynter Blyth, Esq.;* The Vice-Presidents, Secretaries, and Presidents of Branches;* Professor Lane Notter; Professor J. B. Sanderson; Ernest Clark, Esq., F.S.A.; The Editors of THE LANCET; Dr. Ashby; Dr. Barwise; Dr Corfield; Dr. Davies; Dr. Bostock Hill; Dr. Loane; Dr. Campbell; Dr. Munro; Dr. Russell; Dr. Robinson; Dr. Stopford Taylor; Dr. George Wilson; Dr. George Turner; Dr. G. B. Longstaff; Dr. Farquharson, M.P.; Dr. Klein; Dr. Matthew Hay; Dr. Newsholme; Mr. Harris Butterfield; Mr. M. A. Adams; Mr. Keith Young; Mr. Jno. Hamer; Mr. Ernest Turner; Dr. Jas. Niven; Mr. G. H. Fosbroke; Mr. C. E. Paget; Mr. F. Vacher, F.R.C.P.Edin.; and others.

* Representing the Society of Medical Officers of Health.

THE PHYSIOLOGY OF DREAMS.

To the Editors of THE LANCET.

SIRS,—I have read with great interest your annotation on the Physiology of Dreams, but unfortunately did not hear the lecture on this subject by Dr. Richarsdon, on which your comments are founded. I am unacquainted with the exact views of the lecturer on the subject, but it is generally held that a dream is simply the working of the brain during sleep, when all surrounding objects are removed from the consciousness, so that it seems for the time a reality, and all the circumstances connected with it so vivid in the memory that they can be realised when the waking hour arrives. The relating of this dream to another person may occupy some time, so numerous are the incidents, and yet the sleep during which it occurred may be little more than momentary, and herein lies one of the first fallacies with respect to the theory of dreaming. A friend informs me that he has fallen asleep in his carriage, had a dream, and suddenly awoke, when he has found he is not out of the street where his slumber began. For this reason and others which I shall mention it is evident that a dream is nothing more than a mental picture, just as happens when one sits drowsing over the fire in a reverie, and conjures up to the mind's eye some distant spot where one has once been, and with it, perhaps, some well-marked scene, until one is living again in the place as if it were a reality. If true sleep should occur, and so all surroundings cut off, the picture becomes still more real, we become a part of it, see the people move about and hear the music play. I believe the dreamer does nothing more than this; he has a picture before him such as we may see in our National Gallery in "The South Sea Bubble" or "The Derby Day." If he had witnessed these scenes himself only for a minute in a rapid drive through the city or on Epsom Downs it would take a long time to relate all the particulars of the pictures implanted on his mental vision. So I take it in a dream; there is a mental picture of this kind, but the narrator does not describe it as such, but relates a number of incidents occurring over a lengthened period of time, among which are conversations about the names and character of people of whom the dreamer obtains information, there is beautiful music, there is an improvisatore who recites, and various foreign languages are spoken. The narrator of the dream may relate even how he is asked a riddle, and giving it up often obtains the answer from the interrupter; or tell again Boswell's story of Dr. Johnson, how a controversy takes place in which the dreamer has the worst of it. In this case Boswell reminds Johnson that he personified both parties. This, however, afforded no explanation of the fact that in acting the part of two people he was quite unconscious of being the same individual. I take it that it is quite impossible when a person acts the part of two individuals in a dialogue, that he can for a moment forget his personality. I cannot conceive of the possibility of this, nor can I conceive how, during sleep, the mind could pass through such different stages; but this many persons think they do in a dream.

There is one obvious case which shows the fallacy of the ordinary opinion as to the nature of dreams; it is one which sorely perplexed one of my students. He told me that he had been for a short time to a school in Germany, but not long enough to acquire a mastery of the language, whilst of course his master spoke it perfectly. He had often in his dreams returned to his school, when in conversation with his master he spoke only his broken German, whilst his master made use of the best idiom. It greatly puzzled my friend, who, knowing that the dream originated in his own brain, how in his sleep he could be acquainted with the perfect foreign language. I asked him to repeat something which the master had said. This he failed to do, and this is always the case with the relators of dreams; they forget the foreign language spoken, they forget the music they heard, they forget the poem they heard recited, they remember only some triviality or absurd expression which they put into somebody's mouth. Nothing is too extravagant for a dreamer to say has occurred in his dream, and yet he fully believes that his own brain has concocted it. Although he knows not a note of music, he says, in fact, that his brain has produced the most wonderful melodies; although he knows no foreign language, his brain has developed people who spoke them; although he never wrote a verse, his brain during sleep conceived of a lady who recited a charming poem. The absurdity of this common opinion is almost too obvious to be mentioned, and yet there are persons who gravely speak of these things occurring during sleep. The fact of their never remembering a word of these performances when awake does not altogether convince them as it ought, that they never could have had such dreams as they describe. What is usually said is that the mind during sleep conjures up a variety of scenes and performs, as it were, itself the various parts of the different actors. This is what I deny; the student in his sleep did not talk inferior German, and his master the perfect language. All he did was to picture to himself two people with these different characteristics. He never in his dream talked to his master or his master to him. This is simply the way he describes the picture in his waking hours.

In endeavouring to study the physiology of dreams, and the various causes which give rise to them, the first thing to realise is that the whole thing is a delusion; to know that the narrator who says he has been dreaming all night long of certain incidents as if it was a continuous story is deceiving himself; he has merely had a strong mental vision in which the characters have had more reality than in any picture of a scene he can call up in his waking hours. All the living action is a subsequent interpretation. I am not denying the fact of "unconscious cerebration," or that the brain may not solve problems during sleep to be made use of when the subject awakes; nor would I deny that poets or musicians may have shown their respective powers during sleeping hours. A musician may in his fancy have seen the Devil at the foot of his bed performing a tarantella which he wrote down in the morning; or Coleridge might, in a dreamy state at night, compose his "Kubla Khan," but the poem he wrote during his waking hours was the offspring of his "vision in a dream." One difficulty in obtaining a clear idea of the dreaming process appertains to the difficulty which exists, and, perhaps, always will exist, in the explanation of all mental phenomena, and that is, that in operations of the brain and mind we are obliged, from the necessity of our existence, to put the "ego" anterior to all mental processes.

I am, Sirs, yours faithfully,

Grosvenor-street, May 7th, 1892. SAMUEL WILKS.

PSILOSIS.

To the Editors of THE LANCET.

SIRS,—In your observations in THE LANCET of April 30th on Dr. Thin's paper on Psilosis, read recently at the Royal Medical and Chirurgical Society, you remark that his suggestion that the colouring matter of the fæces in these is destroyed low down in the intestinal canal by bacterial action, and, until some other agency has been discovered or this theory shown to be untenable, we must conclude that the views hitherto held as regards the white stools, although probably correct in the majority of cases, are not complete, and that further investigation is necessary before the matter can be satisfactorily settled. My attention was drawn to this question in Jamaica thirty years ago, when studying the character of yellow fever.[1] In that disease, on the fourth and fifth days, the stools are either nearly colourless, or contain merely a small quantity of fetid mucus with more or less biliary matter, but altogether without the appearance of the natural healthy evacuation, and at the same time there is much oppression, great irritability of stomach, and threatening of black vomit. At this stage a brown feculent evacuation of healthy appearance frequently occurs, when the unfavourable symptoms disappear as if by magic, and the convalescence is generally rapid. Here the brown evacuation is evidently a critical discharge of a most important description, and though it may contain bile that is not the cause of its colour, and the presence of such bile does not seem to explain its wonderful influence in removing the fever at its most threatening period.

The general belief of the medical profession is undoubtedly the old one, that pale stools are the result of either the non-secretion of bile, or its retention in the liver itself by obstructed ducts; but the brown colour of the fæces is not due to any modification of that of bile, but to a secretion that is not met with above the cæcum, and is to be found in it in cells impregnated with it, these cells being generally diffused through its more or less fluid contents, and, in favourable specimens, many of them may be found in tube casts, and evidently secreted by the glands in the lining membrane of the organ itself, as the gastric juice is secreted in those of the stomach. It may be asked, if non-secretion of bile or its retention in the liver be relieved by mercurials, and the proper colour of the feculent discharges return after their use, does not this prove the view here advocated to be erroneous? This is not so, however, for the Commission at Edinburgh, which examined, a good many years ago, how far mercurials increased the biliary secretion, showed that they did not do so; yet the action of calomel in moderate quantities on the cæcum and colon is to deepen the brown colour, and to increase these secretions, thereby augmenting their eliminative action, and so relieving any organ behind them from congestion or other disturbance of function which it is possible for an increase of the natural eliminatory process to afford. I am, Sirs, yours faithfully,

ROBERT LAWSON,
London, May 6th, 1892. Inspector-General of Hospitals (retired).

THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editors of THE LANCET.

SIRS,—The Association of Members of the College of Surgeons has already suffered enough for having taken Mr. Lawson Tait's advice in reference to the recent action (Steele *v.* Savory) without having further thrust upon it the responsibility of depriving the College of that gentleman's valuable services upon the Council. The Committee of the Association, desiring to ascertain the extent of their liability as soon as possible, passed a resolution to the effect that, the action having now terminated, the services of the solicitor would no longer be required, and requesting him to send in his account. One of the secretaries, who was brother to the solicitor, took offence at this, and resigned; the other then did likewise, on the ground that he had not for a long time undertaken any of the active duties of the office. Such is the sum total of the "behaviour" which, it seems, is to prevent Mr. Lawson Tait's further candidature for the Council. It is probable that the reason given will appear to his supporters among the Fellows a trifle inadequate, and that his action will seem to lack that "earnestness and wisdom" whose absence in others has so seriously affected him.—I am, Sirs, yours faithfully,

May 10th, 1892. W. G. DICKINSON.

To the Editors of THE LANCET.

SIRS,—I wish, with your permission, to make a few observations upon the letter from Mr. Lawson Tait in regard to the Council of the Royal College of Surgeons of England, published in your last issue. I happen to be a member of the Fellows' Association, and I have always understood that the objects of that Association were to advance reforms in the Council of the College solely *in the interest of the Fellows.* Entirely with that impression, therefore, I recorded my vote in Mr. Lawson Tait's favour at the last annual election to the Council, and also because Mr. Lawson Tait was one of the candidates recommended by the committee of the Association. We now, however, learn from Mr. Lawson Tait that "on the occasions when I have been a candidate in past years I have had the requirements of the Fellows as the chief part of my programme, *but I have always declared that the interests of the Members have largely entered into my reasons for wishing to obtain a seat on the Council.*" When and where, I should like to ask, has Mr. Lawson Tait declared to the members of the Association that his main purpose of gaining a seat on the Council was that of advancing the interests of the Members.

I for one certainly knew nothing about this avowal of his political faith when I voted for him last July, and I certainly should not have voted as I did had I known the real reasons which impelled him to become a candidate. There is no other conclusion possible with regard to the Members' question at the present time than this—namely, that it is not ripe for solution. Why, then, waste time over it? Why attempt the impossible? Reforms such as the Council will be disposed to grant will be first in the interests of the Fellows, and therefore, sheltered behind its powerful charters and by-laws, the Council can now well afford to regard—truly, perhaps—with irritating equanimity the futile attempts of those who endeavour to thrust the Members' question before it. But as soon as the position of the Fellows becomes improved in the government of the institution, for which the Association is now doing its best to strive, then the lesser element of the "body corporate" would be able to help the greater, and to lend its aid to the advancement of those general reforms which are urgently called for in the interests of the College. But I have another bone to pick with Mr. Lawson Tait. He refuses to stand as a candidate of the Association at the next election, and lets us into the secret of a little family quarrel which he has had with the committee of the *Members'* Association, to which, I believe, he belongs. The effect of this quarrel may be given in his own words: "*I have no longer any reason sufficient to induce me to make the* sacrifice of personal comfort and professional income which a seat on the Council of the College would involve. Therefore I shall not offer myself again in July." In short, to use a vulgar expression, Mr. Lawson Tait will see the Association of the Fellows "hanged first" before he will pose as its candidate, now that his own objects in furthering the interests of the *Members* cannot be attained. A curious commentary is this decision of Mr. Lawson Tait upon the fact that for three years he has been the adopted candidate of the Fellows' Association for a seat on the Council, pledged to press forward those points of reform which the Association has always consistently adopted as its programme. Now, however, that Mr. Lawson Tait has made such a plain statement of his creed in this matter, how will his connexion with the Association of Fellows stand? That is certainly a matter which calls for the consideration of the committee of the Association, and to that body it may be left. Meanwhile, I may take this opportunity of congratulating the committee in having secured so thoroughly a desirable candidate as Mr. Tweedy to represent the views of the Association at the coming election. No better choice could have been made, and all the members

should loyally work to ensure his return. In all cases the italics are mine. I am, Sirs, yours truly,

May 10th, 1892. F.R.C.S.

THE LATE MR. CHARLES HAWKINS.

To the Editors of THE LANCET.

SIRS,—In your obituary published on the 10th of April it is stated that when Mr. Hawkins presented himself to the governors of St. George's Hospital as a candidate for the office of Assistant Surgeon he was unsuccessful, "although he had the powerful support of Sir Benjamin Brodie." I am in a position to state that Mr. Hawkins neither solicited nor received Sir Benjamin Brodie's support on that occasion. Mr. Hawkins then displayed the same independent and chivalrous spirit which was so characteristic during the whole of his professional life. During the election Sir Benjamin Brodie had numerous applications from friends to know which way they should vote, and a word from him would have been conclusive with regard to the result. He however, remained strictly impartial.

I am, Sirs, your obedient servant,

Savile-row, May 9th, 1892. HENRY LEE.

"OPERATION FOR SPASMODIC TORTICOLLIS."

To the Editors of THE LANCET.

SIRS,—If Dr. Harkin had in the first instance only referred to the process of blistering as one which ought to be tried before operation was resorted to for this affection, no objection, I think, could have been raised to his letter; but his attack upon the performance of the operation was most unreasonable and unfair. The evidence of published cases, so far as I am concerned, shows that every means known to myself and to the many other medical men who had treated the cases previously had been put in practice before I resorted to operation. In the future, should opportunity occur, I shall certainly not neglect to try the effect of blistering; but I shall be agreeably surprised if it proves to be an effective cure in *long-standing* cases. That it has failed at least in one such case is a fact which has lately come to my knowledge. Should this and the other simple remedies fail to relieve the patient, I shall still think it justifiable to resort to operation.

To answer all Dr. Harkin's objections would encroach too much on your space, so I limit my remarks to the main points. As to his observations about these operations being "painfully like vivisection, from which even the inferior animals are saved by legal enactment," I would remark that in seven out of eight operations the wounds healed by first intention in less than a week, and that the patients suffered no pain or inconvenience worth mentioning. In one instance the wound was somewhat tedious in healing—owing, I believe, to the patient's weak state of health—but it healed up gradually, leaving very little scar. It is possible that in these long-standing cases some central lesion exists which maintains the spasmodic action. This was so in the case of a fowl, the description of which appears in the Transactions of the Pathological Society, vol. xxvi., p. 252, and, if the same condition exists in the human subject, the *rationale* of operation upon the nerves becomes apparent. I am, Sirs, yours truly,

Queen Anne-street, May 7th, 1892. NOBLE SMITH.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Sad Death of a Roman Catholic Priest.

THE Rev. Father Spencer, a well-known and most deservedly respected Roman Catholic priest, died on the 7th inst. under very sad circumstances. The reverend gentleman had for some years past suffered from angina pectoris. On the evening of the day mentioned he was in his residence, the presbytery of St. Clare's Roman Catholic Church, when he was informed by a lady that a man was in the church rifling the alms box. He ran out and seized the man, who escaped. Father Spencer pursued him for a short distance, and then fell down heavily in the road. He was raised up, placed on a couch, and medical aid sent for, but he expired shortly after his fall. The coroner has decided that an inquest is unnecessary. The deceased has resided in or near Liverpool for many years past, and he will be greatly missed both by rich and poor.

Restriction of the Sale of Intoxicants or of Personal Liberty.

However much one may lament the necessity to check freedom by increased legislation, it is evident that some restriction must be placed either upon the sale of intoxicants or upon the liberty of those who indulge in them too freely. In one day last week the city coroner held inquests on the bodies of four persons who had died from various diseases due to excessive drinking. Since then the deputy coroner has held a fifth inquest, the facts being precisely similar. The money spent in drink would enable the unfortunate men and women afflicted with this terrible curse to live in decent comfort, and there are in this city many of these to whom it would be a charity to remove them from their present surroundings to some place of restraint. The fatalities of intemperance, though a terrible feature of the evil, constitute only a very small part of it, and its worst effects fall most frequently upon soberpeople.

The Lock Hospital.

IN THE LANCET of April 30th there is reported the case of a man who was admitted into the London Lock Hospital, the whole of the penis having been lost by sloughing of an ulcer. A somewhat similar case was admitted into the Liverpool Lock Hospital some weeks ago. The patient, who was a fireman on board a steamer, had suffered from an ulcer of the penis; whether this were chancre or chancroid, or whether what followed was sloughing or phagedæna, could not be ascertained. On admission the whole of the penis was gone, leaving a large and unhealthy-looking surface, which, however, rapidly yielded to the local application of iodoform in fine powder applied by means of a pepper-box. The patient left the hospital before the healing process was quite complete in order not to lose his situation. Mr. Lowndes, whose patient he was, has another male patient in whom a considerable portion of the glans penis had sloughed away before his admission. The same treatment had a very beneficial effect, the sloughing process being arrested at once. Mr. Bernard has a female patient suffering from tertiary syphilis in a very severe form, and several severe forms of secondary syphilitic eruptions. He had recently a male patient who had lost more than half of the soft palate on his admission, and though the admissions into this hospital have not, for various reasons, been so numerous as formerly, they have been quite as severe.

Liverpool, May 10th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Royal Infirmary.

THE vacancy on the staff of the Royal Infirmary caused by the death of Dr. Ross, and the consequent promotion of Dr. Harris to the full physiciancy, was on Monday last filled by the election of Dr. A. T. Wilkinson, who at a previous period had for nine years held the post of assistant medical officer to the same institution. The entries of new students for hospital practice were fewer this year than they were last summer. Registration took place during the last days of April, but much time is lost by students delaying to register until the latter half of May, and thus missing the early lectures of the short summer session. The numbers may therefore still reach those of previous years.

Victoria University.

The newly elected Chancellor of the University, Earl Spencer, is to be installed on May 25th. The ceremony will take place in the Town Hall, and the occasion is to be one of full academical dress. There appears to be much anxiety to obtain tickets, and the room will in all probability be crowded. There are few occasions which bring the existence of a University in Manchester before the general public, and this may be the cause of the great interest shown in the forthcoming ceremony.

Epidemics.

The threatened small-pox epidemic has subsided, and since the middle of April no new cases have been reported.

Digitized by Google

At the end of April there were still six cases in hospital, and the number has now fallen to three; none have ended fatally. The danger may therefore be regarded as past. Cases of influenza are still appearing, but the number of new ones was only four in the last week of April, though the deaths certified as due to that malady were higher than in the preceding week, when the new cases were thirteen in number. This apparent discrepancy may depend in part upon the care taken by practitioners in obtaining the history of the ailment in individual cases, as there is among patients here a great tendency to attribute any illness from which they may happen to suffer to a previous attack of influenza.

Manchester, May 11th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Newcastle Royal Infirmary and the Strikes.

AT a late meeting of the governors of the Royal Infirmary, in reference to the decrease in the workmen's subscriptions owing to the strikes, it was stated that, considering the very large number of men out of work, the decrease was not larger than might have been expected, so it was evident that those in work had done their duty to the infirmary. The resolution of sympathy with the family of the late Dr. Bruce, and of tribute to the deceased gentleman's work, which was passed by the court on the 7th ult., was confirmed. With reference to the strikes and the medical charities generally, it may be stated that in the Elswick works the amount subscribed for the quarter ending April last was only about £200, against about £300 in the previous quarter, before the engineers' strike now happily at an end. All the other medical charities have suffered in proportion.

Ambulance Work in the North.

At a public meeting held at West Hartlepool last week, at which the Mayor presided, Mr. Swanwick was the recipient of a testimonial and presentation. He was thanked most heartily for giving lectures and conducting ambulance classes, and Sir William Grey, in making the presentation of library books, spoke in warm appreciation of Mr. Swanwick's work. Dr. W. Turnbull's course of fourteen ambulance lectures to the Newcastle Wholesale Coöperative Society's *employés* was brought to a close last Thursday. Dr. H. S. Baumgartner of this city was the examiner, and at the close complimented the class on their efficiency and Dr. W. Turnbull on the thoroughness of the instruction given. Dr. Mears has announced a course of ambulance instruction to be given at the Sailors' Home, North Shields, to captains, engineers, officers, and sailors. The course is to consist of five lectures.

The New Asylum for Sunderland.

A deputation from the Town Council of Sunderland has gone to London to confer with the Commissioners in Lunacy with reference to the plans for the new asylum at Ryhope, the Commissioners having suggested certain alterations costing not less than £5000, and the deputation has been appointed to urge strong reasons against these proposals.

Measles in the Darlington Rural Sanitary District.

At a late meeting of the Darlington rural sanitary authority, in the course of a discussion on the prevalence of measles and its notification, Dr. Eastwood said that there were more deaths from measles than any other disease during the quarter. It was more fatal than scarlet fever. If they did not keep one on the list, he did not see why they should keep the other. It was also stated that measles cost three times as much as the other diseases.

The Bowes Museum, Barnard Castle.

Any of your readers thinking of taking a holiday in Whitsun week, and likely to get into the lake district, should try to run over the fells into Yorkshire and see the opening of the Bowes Museum in Barnard Castle. This magnificent building is stored with costly treasures of art and natural history. The opening too will be public.

A Durham Centenarian.

Last Thursday, Mr. Walter Brodie of Low Downs, near Hetton, attained his 100th birthday. He was born in Northumberland, but removed to the neighbourhood of Hetton, where he worked as a miner for eighty-two years. He is said to retain all his faculties with the exception of his eyesight, which is rather feeble. He has a son aged seventy-four, who only gave up his employment as a miner about six months ago, on hearing which, it is said, the old man addressed him thus in a stern and peremptory manner: "Thou should think shem o' th' sell at thy age; thou's only a lad, and talking about giving up wark. Think shem o' th' sell."

Charitable and Scientific Bequests.

It is stated that the late Mr. J. H. Fox, brewer, of Norton near Stockton, has directed to be set aside the handsome sum of £20,000 to erect and endow almshouses for the village of Norton. A condition attaches to the bequest, and it is that it can only operate provided some one gives the necessary land within twelve months.

The late Dr. Heath and the Newcastle College of Medicine.

It is now freely stated that the late Dr. Heath has left about £19,000 for different purposes in connexion with the College of Medicine in this city—viz., £6000 for the endowment of a chair of Comparative Pathology; £5000 to erect residences for students attending the college; and about £8000 for specific purposes in connexion with the college, which cannot be particularised as the will has not yet been proved. I hear that Mr. Frederick Page, formerly a colleague of Dr. Heath and at present one of the surgeons to the Royal Infirmary here, is one of the executors.

Newcastle-on-Tyne, May 11th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Edinburgh Medico-Chirurgical Society.

AT the meeting of this Society last week Mr. Caird showed a case in which the olecranon had been successfully wired for simple fracture. An important paper was communicated by Dr. Macpherson of the Larbert Asylum, and Dr. David Wallace, Edinburgh, on the Surgical Treatment of General Paralysis of the Insane, with five illustrative cases. The patients were under Dr. Macpherson's care, and the operations were performed by Dr. Wallace. The paper reviewed the pathology of the disease, and discussed the views held as to the nature of the primary disturbance, the authors giving their adhesion to the inflammatory view. The cases were all well-marked instances of the disease. In most of the cases about a square inch and a half of bone was removed from both sides from over the inferior fronto-parietal region. Surgically the cases, without exception, did admirably, all of them healing by first intention. As regards the effect upon the disease itself there was a degree of improvement in the symptoms a short time after the operations. The improvement, however, was of a temporary character.

Scottish Microscopical Society, Edinburgh.

This Society met last week. The meeting was almost wholly occupied by Dr. Carlier, who gave a microscopical demonstration of various organs taken from the hedgehog during hibernation, and compared them with the same organs during summer. The most interesting point brought out, and dwelt upon both by the reader of the paper and the speakers on it, was the occurrence of a profuse migration of leucocytes into the mucous and submucous coats of the greater part of the alimentary tract and round the ducts opening into it. Dr. Carlier regarded this as a proof of the phagocytic function of these cells, and considered that the migration was the means of preventing the invasion of the tissues by the microbes in the intestine—an invasion which would almost certainly take place when the body temperature was so lowered were it not for this provision.

Death of the Rev. John Lowe, F.R.C.S.Edin.

On Monday morning the profession in Edinburgh was startled by the intimation that Mr. Lowe had died suddenly the previous evening. Mr. Lowe was well-known in Edinburgh as the superintendent and secretary of the Training Institution of the Edinburgh Medical Missionary Society. Early in life he went as a medical missionary to Travancore, but was appointed in 1871 to the post he occupied at the time of his death. As an author he was known as the writer of "Medical Missions, their Place and Power," and

Digitized by Google

a "Life of Dr. Elmslie of Cashmere." He was a man of a quiet and unobtrusive nature, kindly and friendly in manner, and much esteemed by those who were brought into close contact with him in medical mission work. It is understood that he died of cardiac syncope when suffering from some trifling ailment, and that his death was as unlooked for by those around him as by others.

Health of Edinburgh.

The mortality last week was 85, making the death-rate 17 per 1000. Chest affections caused 35 deaths, and zymotic diseases 5. The intimations for the week were: typhoid fever, 5; diphtheria, 1; scarlet fever, 24; measles, 39.

(FROM OUR OWN CORRESPONDENT.)

Presentation to Mr. H. Gray Croly, P.R.C.S.I.

A PRELIMINARY MEETING was held at the College of Surgeons on the 6th inst., for the purpose of forming a committee to carry out the proposed presentation to Mr. Croly, President of the College. It is intended to present him with his portrait as a mark of esteem from his professional brethren and as a memorial of having filled the presidential chair for a period of two years in a dignified manner, and for his great hospitality. The honorary secretaries are Mr. Henry Sherlock, F.R.C.S., and Mr. R. Montgomery, F.R.C.S.; while Mr. J. O'Donovan, F.R.C.S., of Kingstown, will act as honorary treasurer. About one hundred gentlemen have intimated their intention of taking part in the presentation.

Royal College of Surgeons.

Mr. William Colles, senior member of council, has resigned his seat, and a by-election to fill the vacancy will be held on Monday next, the 16th inst. The following are candidates—viz, Mr. Auchinleck, Mr. Arthur H. Benson, Mr. Broomfield, Dr. Cranny, and Mr. George Foy. Mr. Colles resigns also the secretaryship of the college, and for this high and honourable office the two candidates are Sir Charles Cameron and Mr. Austin Meldon, both of whom are ex-presidents of their college. Sir Charles Cameron considers that a candidature for such an office should be based upon services rendered to the college, and undoubtedly in this particular he can show a very high record. By his exertions the taxation of the college was reduced by about £140 a year; and by his influence Mr. Dease presented the statue of the late Surgeon Dease, first professor of surgery, which adorns the college hall, and the late Mr. Butcher gave his valuable collection of casts to the college, while Mr. Dease provided, at his suggestion, a room for the reception of the casts, and also a suite of laboratories for the college curator at a cost of £1200. Further, he spent a large portion of his time for three years in writing the history of the college without any pecuniary recompense. Again, on his motion a new charter was obtained admitting women to the privileges of the college; and it was Sir Charles Cameron who originated the scheme of combining the examinations of the college with those of the Apothecaries' Hall, which last year benefited the college by a sum of nearly £450. Lastly, at his suggestion the college instituted a diploma in Public Health, and he obtained for it the privilege of having that diploma registered. The election for the secretaryship will take place the first Monday in June.

Meath Hospital, Dublin.

The medical and surgical prizes obtained at the termination of the winter session were awarded to the successful students this week. The first medical prize was obtained by Mr. C. E. Stokes, and the second prize by Mr. A. McCutcheon. Sir George Porter, Bart., in distributing the surgical prizes, said that the answering in the senior class was of a very high order, and the competition so close that the board determined to give three prizes instead of two as heretofore. Mr. Wm. Taylor was awarded the first senior surgical prize, Mr. F. Warren the second, and Mr. C. Stokes the third prize.

Dublin Main Drainage.

A special meeting of the Corporation was held last Monday with reference to the drainage of the city. The ordinary borrowing powers of the council are insufficient for the sum required for a Main Drainage Scheme (£278,000), and they have therefore resolved to send a deputation to the Chief Secretary to request that the Government shall this session introduce a Public Act declaring that the expenditure on the Main Drainage Scheme shall not be restricted by any of the regulations contained in section 238 of the Public Health Act (Ireland) 1878, and in calculating the amount which the Corporation may borrow under that Act any sums which they may borrow for the purpose of main drainage shall not be reckoned.

Exclusion of Irish Diplomates from English Hospital Appointments.

The following resolutions have been passed by the Council of the Irish Medical Association:—"That the Council of the Irish Medical Association, having had their attention called to a resolution adopted by the governors of the East Sussex Hospital, by which a rule is perpetuated which limits to the diplomates of one London college the appointment of hon. physician to that hospital, and having observed the published statement made by certain of the governors derogatory to the professional status of Irish diplomates, hereby protests against such statements as being inaccurate in fact and unjust to Irish diplomates practising in England. That the Council have, by inquiry, satisfied themselves that there is no ground for these aspersions upon the professional competency and social status of Irish diplomates, and they do not hesitate to assert that, in the extent and nature of the courses of study and of the examinations essential to obtain their diplomas, the requirements of the Irish colleges are fully equal to if not in excess of those of the colleges in London or elsewhere; and that Irish diplomates are, in all respects, well fitted to occupy a position on the medical staff of a public hospital in England or elsewhere. That the Council of the Irish Medical Association are willing that Irish diplomates shall rest their claims for professional advancement upon their own merits, and therefore desire that the governors of hospitals in England shall be free to select the physician or surgeon whom, all things considered, they approve; and the Council therefore protest against an arbitrary restriction of that freedom of election in favour of any medical licensing body whatsoever."

Death of the Oldest Woman in Ireland.

An old lady named Margaret Harpur died recently in the county Wexford at the great age of 110 years, the deceased being regarded as the oldest woman in Ireland. She was born in the year of the volunteer movement, and was in her seventeenth year in 1798, the year of the rebellion, of many incidents of which she had a lively recollection. Her health has been wonderfully good until within the last two years, when her mental faculties became impaired; but she was not confined to her room until last November.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Ovaro-Salpingitis as a Complication of Measles.

As I cannot discover any allusion in the works of classical English authors to the above condition as a complication of measles, M. Galliard's communication to the Société Médicale des Hôpitaux (April 22nd) may be found interesting. The patient was an unmarried woman of twenty-five years, who had never suffered from any affection of the genital organs. About the sixth day after the invasion of measles menorrhagia set in. On the thirteenth day the temperature rose, and the patient complained of pain in the right iliac fossa, while tympanites appeared. On the twenty-second day M. Monod performed abdominal section. The incision gave issue to a quantity of pus, and the inflamed intestines were found to be already covered with false membranes. No purulent collection was discovered in the iliac fossa. The drainage of the peritoneal cavity was provided for after the toilette of the serous lining had been practised. The woman died on the twenty-sixth day; the pus evacuated contained streptococci. Post mortem the heart was found healthy, one ovary was swollen and was the seat of four small abscesses. The Fallopian tube was dilated and surrounded by false membrane; in its lumen was found a certain quantity of pus. In the dis-

Digitized by Google

cussion that followed, M. Comby asked if M. Galliard was sure that the lesions discovered were not secondary to vulvitis—a common condition in the course of measles. To this query M. Galliard replied that although the vulva and the vagina were certainly congested, the external genitalia were not the seat of suppuration. M. Rendu could hardly bring himself to believe that the suppurative process in the ovary and the tube was caused directly by the attack of measles. He was inclined to think that any infectious disease might produce a similar lack of resistance in the viscera. This view was supported by M. Chantemesse, who recalled two instances of such a complication (ovaro-salpingitis) occurring in the course of typhoid fever. For my part, I am inclined to think that if a minuter examination of the genitalia had been made, the *porte d'entrée* for the streptococcus would have been found. Should it not be the rule to scrupulously disinfect *all* mucous orifices in cases of zymotic disease? Medicine is becoming more and more alive to the truth of the aphorism, "Cleanliness is next to godliness"; and it is certain that these secondary suppurations would become *rarœ aves* if ordinary antiseptic precautions were taken to bar the entrance into the lymphatic system of the micro-organisms which are ever on the watch to fix on one or several organs as a nidus for their growth.

A New Symptom of Paralysis of the Laryngeal Muscles.

M. Fauvel states (Société Française d'Otologie et de Laryngologie) that whenever a patient whose voice is either extinct or bitonal and harsh has, in addition, a breath which is offensive and alliaceous, paralysis of the muscles of the larynx may be confidently diagnosed. For several years past M. Fauvel has remarked the constancy of this symptom, the presence of which is due to the decomposition of the mucus stagnating on the surface of the membrane. The odour is *sui generis*, and totally unlike any other. To practitioners unaccustomed to the management of the laryngoscope this phenomenon may be useful in leading them to a correct interpretation of concomitant symptoms referred to the larynx.

The Therapeutical Application of Cycling.

In the current number of the *Semaine Médicale* there appears a valuable contribution to our knowledge of cycling as a therapeutical agent from the pen of our compatriot, Dr. Oscar Jennings of Paris. Dr. Jennings is well known as an enthusiastic advocate of this most pleasant form of exercise, and his opuscule, "La Santé par le Tricycle," is widely read in the different languages into which it has been translated. The paper in question is full of information concerning the advantages to be derived from cycling in such divers maladies as gout, rheumatism, metritis, obesity, phthisis in the first and second stages, asthma, diabetes, dyspepsia, hypochondria, neurasthenia, agoraphobia, &c. No one who carefully reads Dr. Jennings' paper can avoid coming to the conclusion that a large proportion of the sufferers who crowd the waiting-rooms of fashionable physicians would soon forget much of their troubles were they wise enough to take a daily spin on an easy-running machine. It is characteristic of the altered views held on the subject of the treatment of cardiac affections to see cycling actually recommended for this class of cases. Sir Walter Foster states that in aortic insufficiency it is important to increase the frequency of the cardiac pulsations, and most people will agree with Dr. Jennings in regarding gentle cycling as a pleasanter form of exercise than the climbing of mountain slopes advocated by Oertel.

The False Alarm of Cholera in Paris.

In my letter of a fortnight ago I felt it my duty to contradict a disquieting rumour of the appearance of cholera in this capital. The outbreak was a purely local one, being limited to such outlying villages and districts as Nanterre, Neuilly, Puteaux, and Levallois-Perret. Professor Proust has just furnished a circumstantial report on the occurrence to the Comité Consultatif d'Hygiène. The disease was simply cholera nostras, but sufficiently serious to determine a fatal result in forty cases out of a total of sixty-two. The epidemic first made its appearance amongst the inmates of the Nanterre hospital, where the sanitary arrangements appear to be in urgent need of reform. The drinking-water is of bad quality, and the feeding insufficient, only 125 grammes of meat being allowed three times a week. The establishment is, moreover, overcrowded, housing as it does double the number for whom accommodation was originally provided. No cases of genuine cholera have been seen in this city for the past seven years. This outbreak of choleraic diarrhœa occurred entirely outside Paris, and ceased altogether on the 20th ult.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

A Practical Triumph of Bacteriology.

NEWS arrived some weeks ago of a plague of mice, which threatened to destroy the whole harvest in the Thessalian plain. Terror seized all Greece, for the Thessalian harvest is the greater part of the total harvest of that country, and all means were tried to put an end to the plague. The ignorance and superstition of the peasants, however, frustrated all attempts, and ruin seemed inevitable. Following Pasteur's advice, it is said, the Greek Government called in the aid of the well-known German bacteriologist, Professor Löffler of Greifswald, who has put an end to the plague by causing a fatal pandemic among the mice.

Stoking in the Tropics.

The maritime courts frequently have to deal with cases of stokers who spring overboard in the tropics, and Dr. Arnold Kurrer, assistant in the Pathological Institute at Kiel, has made a special study of this form of suicide. On a voyage from Hamburg to Java he carefully observed the temperature of the stokers, the simultaneous temperature of the engine-room and the outer air, the motion of the air, and other climatic circumstances. Only Hindus were employed as stokers on board his ship; but he has informed himself of corresponding phenomena in the case of European stokers. He found that stokers of both races are exposed in the tropics to such heat that their health is very often seriously impaired, even not unfrequently to the danger of their lives. The enhancement of the animal heat is considerably influenced by the motion of the air. The Hindus generally suffer less than the Europeans, who often do themselves much injury by wearing unsuitable clothes. The increase of animal heat in the Hindu stokers is remarkably uniform, but differs greatly among the Europeans, owing, as Kurrer thinks, to a special disposition of the latter, produced by alcohol, malaria, and diseases of the skin and the vessels. He advises that European stokers should not be employed in the tropics, and that only such as have perfectly healthy lungs and skins should engage in the work. First-rate ventilation is, of course, of paramount importance. It seems strange that, in this age of ingenious inventions, no method of automatic stoking has yet been introduced. It would be of much greater value to mankind than the phonograph.

Berlin, May 10th.

Obituary.

CHARLES ROBERT SMITH, M.B. CANTAB., M.R.C.S.

THE death of this gentleman took place at his residence in Darlington-street, Wolverhampton, on the 27th ult. He was forty-one years of age, and a bachelor. He received his early education at the Wolverhampton Grammar School, and completed it at Cambridge, where he gained honours as a Wrangler, being eighteenth in the list. He also took the degree of M.B., and obtained several University prizes. He returned to Wolverhampton about 1877 and commenced practice in Darlington-street, and succeeded to his father's practice in the Dudley-road on the death of that gentleman, but last year returned to Darlington-street. In 1886 he was elected a member of the Wolverhampton Town Council, and took an active interest in municipal affairs. He will be long remembered for his zeal in promoting the establishment of the local Eye Infirmary, for his association with the Women's Hospital, and also for his connexion with the founding of the Wolverhampton Literary and Scientific Society.

J. M. BEVERLEY, M.D. LOND., M.R.C.S.

MUCH regret will be felt at the early death of Dr. J. M. Beverley, who passed away at the little village of Ospedaletti, Italy, early on Sunday morning, May 1st.

Digitized by Google

He was only thirty-one years of age, and had been for some years in general practice at Littlehampton in Sussex, where he was liked by all with whom he came in contact. His strict sense of duty, careful attention to work, and general kindliness had endeared him to everybody in the neighbourhood. Dr. Beverley had been a brilliant student at the Owens College, Manchester. Last October he was ordered to winter abroad on account of failing health, and since then he has borne with patience and fortitude the rapid advances of an attack of phthisis, to which he succumbed a few days ago. He leaves a wife and two children.

PROFESSOR AUGUST WILHELM HOFMANN.

CHEMISTS have lost an able and eminent investigator in the person of Professor Hofmann. This distinguished *savant* died in Berlin on the 5th inst. His name will ever be linked with the discovery of some of the most beautiful dyes science has produced. Aniline red, indigo, and Hofmann's violet may be taken as examples. His well-known simple and accurate method for the determination of the vapour density of substances is made use of by investigators at the present time. After spending three years at Bonn, Professor Hofmann, in 1848, was, on Liebig's recommendation, appointed superintendent at the Royal College of Chemistry in London. The institution made rapid progress under his direction, and in 1853 was merged in the Royal School of Mines as the Chemical Section. In 1855 Professor Hofmann was appointed by the British Government a warden of the Royal Mint. In 1864 he was appointed to the chair of Chemistry at Bonn, whence he was summoned to Berlin in the following year, and he has there ever since occupied the professorial chair of Chemistry. In 1854 he was awarded a Royal medal, richly deserved for his memorable "Memoirs on the Molecular Constitution of the Organic Bases." Professor Hofmann's researches contributed in no small measure to raising the dyeing industry to the high level it has since attained. This alone will stand as an inscription on his monument not easily effaced.

ROYAL COLLEGE OF PHYSICIANS.

AN extraordinary meeting of the Comitia was held on Thursday evening, May 12th, Sir Andrew Clark, President, in the chair.

The Fellows recently elected were admitted, and a communication from Dr. Clement Dukes, of Rugby, was read. The College then proceeded to elect a Bedell in the place of Mr. Gurner, who will retire at midsummer, and on the recommendation of the President, Treasurer, and Registrar, appointed Mr. William Fleming, who has for some twenty years been in the service of the College, formerly as clerk to the Registrar and assistant to the Librarian, and latterly has acted as chief clerk to the Secretary at the Examination Hall. A report from the Finance Committee recommending a retiring pension to the Bedell, Mr. Gurner, was received and adopted, with a slight modification.

Reports from the committee of management dealing with certain conditions of exemption from the College examinations, and also with the arrangements for the First and Second Examinations under the Five Years' Scheme, were received and adopted.

Brief formal business connected with the enactment, alteration, and repeal of various By-laws and Regulations brought the meeting to a close at an early hour.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an ordinary meeting of the Council, held on Thursday, the 12th inst., the Minutes of the quarterly Council, held on April 7th, were read and confirmed.

Mr. Jabez Thomas was introduced, and after signing the By-laws and making the required declaration, was admitted a Fellow of the College.

As recommended by the Jacksonian Committee, the subject of the next Collegial Triennial Prize is to be the Spleen, its Anatomy and Physiology, illustrated by Comparative Anatomy.

The report of the Committee of Management, dated March 28th, was approved and adopted. The following report of the Committee of Management, dated May 9th, was approved and adopted, subject to adoption by the Royal College of Surgeons:—

That the examinations in Chemistry (and Physics relating to Chemistry), Elementary Anatomy, Anatomy and Physiology, under the new regulations, dated Jan. 1st, 1892, be conducted in the same manner as heretofore, and that the examinations in Practical Pharmacy and Elementary Biology do consist of an oral examination with specimens, in accordance with the following regulations: viz.:—

FIRST EXAMINATION.

Part 1: Chemistry and Physics.—There shall be a written paper, for which three hours shall be allowed; and an oral and practical part, which shall occupy not less than thirty minutes.

Part 2: Practical Pharmacy.—There shall be an oral examination, which shall occupy not less than ten minutes.

Part 3: Elementary Biology.—There shall be an oral examination, which shall occupy not less than fifteen minutes.

Part 4: Elementary Anatomy.—There shall be an oral examination, which shall occupy not less than ten minutes.

SECOND EXAMINATION.

Anatomy and Physiology.—There shall be a written paper in each subject, for which three hours shall be allowed, and an oral and practical examination in each subject, which shall occupy not less than fifteen minutes.

The annual meeting of Fellows of the College for the election of members of the Council will be held on Thursday, July 7th, at 2 P.M.

A letter of the 9th inst. was read from Dr. Liveing, reporting the appointment of a Committee of the Fellows of the Royal College of Physicians "to consider and report from time to time on any proceedings relating to the formation of a University for London so long as that subject is under consideration." No special committee was appointed, but it was referred to the President and Vice-Presidents to watch the proceedings of the Royal Commission and report thereon to the Council if necessary.

A letter from Dr. B. C. A. Windle was read, reporting the approaching transfer of the medical school hitherto carried on in Queen's College from that college to Mason College, and requesting that the recognition now extended by the College to the medical school of Queen's College might be transferred to the medical school of Mason College. The request was granted.

A letter of the 23rd ult. was read from Mr. H. Percy Dunn, reporting the following resolution adopted by the Committee of the Association of Fellows, viz.:—"That the Committee of the Association of Fellows of the Royal College of Surgeons, having noticed that the Council of the College has appointed a committee to consider the claims of the Fellows, would suggest that a deputation from the Association should be asked to meet the committee in order to set forth the views of the Association." The following reply was directed to be forwarded: "That the Council do not consider it expedient that their committee should receive any deputation, but that the Council will be glad to receive any written communication from any Fellow or Fellows of the College as to any further advantages, not involving changes in the Charters and By-laws, that might be extended to the Fellows."

The Council decided to purchase a replica of a bust by Mr. T. Brock, R.A., of the late Mr. John Marshall, F.R.S.

THE ELECTION OF CORONERS.—We understand that the election of the coroners to fill the vacancies created by the death of the late Mr. Carter and of the late Dr. Diplock respectively rests in the hands of the Public Control Committee of the London County Council. It is unlikely that the appointment will be made for some weeks, as the Privy Council have not yet sanctioned the proposed severance of Middlesex from the London portion of the existing districts, and the extension of the jurisdiction of each of the three coroners, Mr. Braxton Hicks, Mr. Wyatt, and Mr. Carttar.

Medical News.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the April sittings of the Conjoint Board, held in Glasgow, the following candidates passed the respective examinations:—

First Examination.—Thomas A. Beadle, Durham; John F. Neville, co. Cork; Thomas Gallacher, Port Glasgow; Robert P. Graham, Glasgow; Robert G. Whitelaw, Kirkintilloch; Thomas Shanasy, Adelaide; William M. Sheen, Gravesend; James Boyd, Glasgow; David S. Henderson, Coatbridge; Benjamin Wade, Pudsey; Roger Laverty, co. Down; Wm. H. Curtis, Hampshire; Thomas Wm. Robinson, Limerick; John O'L. Driscoll, Bandon; William Thomas, Glasgow; John M. Beattie, Belfast; George S. R. Stritch, Galway; James James, Cardiff.

Second Examination.—Wm. Edward Jones, Liverpool; Janet Russell Wells, Glasgow; Kate Kirk Paton, Glasgow; Catherine Howie, Glasgow; John Macintosh, Glasgow; John O'Connell, co. Kerry; Thomas Parker Powell, Breconshire; John M'Lean, Glasgow; Alfred H. Mountcastle, Manchester; Alexander Whyte Mason, Glasgow; Joseph A. Blayney, Haslingden; James Fenwick, Accrington; Samuel T. Brooks, Farnworth; Wm. R. Abernethy, Londonderry; Anthony Strong Rose, Morpeth; Robt. P. Snodgrass, Montreal; James Devon, Glasgow; Robert Owen, Carnarvonshire; George Hill, Glasgow; James H. Robinson, Southport; J. F. Wm. Ward, India.—*Anatomy and Physiology:* Ebenezer Allan, Joseph Tibbetts.—*Anatomy:* Edward Denison.—*Physiology:* Joseph P. Woodhouse.—*Materia Medica:* Robert Alexander M. Robinson, Allan Forde, Cecil W. Roebuck.

Final Examination.—Jessie MacLaren Macgregor, Edinburgh; S. I. Williams, Edinburgh; David Edward Richards, South Wales; Henry Gould, Glasgow; James W. Hudson, Millom, Cumberland; Sydney E. Rossiter, Lambton, Durham; Archibald Mackellar, Glasgow; Walter Fisher, Edinburgh.—*Medicine and Therapeutics:* Matthew Marriott, L. Burges.—*Surgery:* Samuel E. Jones, Edward R. Pollard, William E. Blakely, Thomas G. G. Symons.—*Midwifery and Medical Jurisprudence:* E. R. Pollard, Wm. Wardman, John Clark, Rees T. Jones, Thomas C. Hunter.

UNIVERSITY OF DUBLIN.—At a recent meeting of the Senate the degree of Doctor in Medicine was conferred on Alfred Russell Darley.

ROYAL UNIVERSITY OF IRELAND.—The following candidates have passed the Medical Degrees Examination:—

Upper Pass Division.—*Robert Campbell, Herbert Cunningham, Richard Heard. (The candidate marked with an asterisk may present himself for the further examination for Honours.)

Pass Division.—Patrick L. Aherne, Kennett B. Barnett, David J. F. Bennett, Henry R. Corbett, Michael Coughlan, Isaac Davidson, William J. Molloy, Michael O'Sullivan, James R. Thomson.

Doctor in Medicine.—Ambrose E. J. Bermingham.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND: CONJOINT SCHEME.—The following candidates have passed the Final Examination, and if of age are entitled to be admitted Licentiates of the Colleges in Medicine, Surgery, and Midwifery:—

H. W. Cave, M. J. Chevers, J. O'C. Donelan, F. L. Flood, D. H. Foley, P. J. Garland, L. A. Jameson, A. R. Moore, W. W. Scarlett, J. P. Sexton, Temple Smyth, E. H. Tweedy, W. P. Walsh.

The following have passed in the subjects indicated:—

Medicine.—E. A. Guinness, R. B. Hunt, V. E. McDonogh, J. M. O'Callaghan, W. J. Trewhella.

Surgery.—F. C. A. Bushman, W. J. Trewhella.

Midwifery.—A. A. Hargrave, F. O. Stoker, Miss J. Gwynne.

HOSPITAL SUNDAY FUND.—The Lord Mayor has received a cheque for £105 in payment of legacy (duty free) by the executors of the late Dr. H. E. Price of West Brighton.

A WATFORD CENTENARIAN. — The Watford Guardians, at their meeting last week, were informed that Elizabeth Ginger, of Bell-lane, Hendon, had passed her 100th year, and in celebration of her centenary they voted her an allowance of 5*s.* instead of 4*s.* per week, as hitherto.

OPEN SPACES FOR NORTH-WEST LONDON.—The St. Pancras Vestry have resolved to recommend the London County Council to purchase the vacant pieces of land, over two acres in extent, in Highgate-road, by Highgate-road Station. The vestry's recommendation was passed with the concurrence of the Council, who still hold a considerable portion of the £12,000 vested in them for the extension and improvement of open spaces in the parish.

ST. BARNABAS' CONVALESCENT HOME, RAMSGATE.—The annual report for 1891 shows that satisfactory progress had been made by the institution during the year. The year's income was adequate to meet the expenditure and to leave a small surplus in hand; 289 patients were admitted in the course of the twelvemonth. Accommodation is provided for six lady boarders, a branch of the work which had been well tested.

MEDICAL MAGISTRATE.—The name of William Armstrong, M.R.C.S., has been placed on the Commission of the Peace for Manchester.

DR. HEYWOOD SMITH will read to the British Nurses' Association, on Friday, May 20th, at 8 P.M., a paper on the subject of Gynæcological Nursing.

PROPOSED CONVALESCENT HOME AT LEEDS.—A scheme has been started for providing a convalescent home for the West Ward.

FOOTBALL CASUALTY. — A young man aged eighteen, while playing a game on Saturday, on Glasgow Green, fractured his clavicle.

LONDON TEMPERANCE HOSPITAL, HAMPSTEAD-ROAD, N.W.—The Duchess of Westminster, accompanied by the Duke of Westminster, formally opened on Wednesday, in the presence of a large assembly, the "Grosvenor" Children's Ward at this institution—a ward which will supply a long-felt want.

THE SUSSEX COUNTY HOSPITAL.—The largest benefaction ever received by the Sussex County Hospital was announced to the management of that institution on the 9th inst., the late Mr. John Silvani of Brighton having left an immediate bequest of £10,000; while the hospital is also to receive the residue of the estate, which is estimated at £20,000. Several Brighton charities receive £1000 each.

CREMATION IN SCOTLAND.—The report of the directors of the Scottish Burial Reform and Cremation Society, Limited, states that since the company was registered in December, 1890, with a nominal capital of £5000 in £1 shares, over £700 has been subscribed in the past two years towards the £1000 or £1500 considered necessary to enable a start to be made, and the directors are sanguine that in a very short time they will be able to proceed with the erection of a crematorium.

RECOGNITION OF A SURGEON'S BRAVERY. — A meeting has been held in the dining hall at Messrs. Tangye's works for the purpose of presenting to Mr. W. E. Bennett (surgeon to the works) a bronze medal and a certificate awarded by the Royal Humane Society, in recognition of his bravery in saving the life of a man named Samuel Loton on Feb. 29th. Mr. R. Tangye, who presided, explained that Loton was found struggling in the Birmingham Canal, near Rabone-lane bridge. A young lady named Dodd, seeing Loton in the water, ran for help, and, finding Mr. Bennett in the dispensary, told him of the accident. This gentleman hurried to the spot, and plunging into the water succeeded in rescuing Loton, who was unconscious, and Mr. Bennett was also exhausted. After a time Loton was restored to consciousness; and he (the speaker) congratulated Mr. Bennett upon having saved the man's life. Alderman Pollack then made the presentation, which was suitably acknowledged.

CHICAGO EXHIBITION. — The Subcommittee of Nursing and Hygiene for the British Section at the Chicago Exhibition has been formed. It consists of the following members: Lady Jeune, Mrs. Priestley, Miss Shaw Lefevre, Mrs. Bedford Fenwick (who will preside), Mrs. Holmes Spicer (hon. sec.), Miss Isla Stewart, Matron and Superintendent of Nurses, St. Bartholomew's Hospital (adult nursing); Miss Lumsden, Hon. Superintendent, Royal Infirmary, Aberdeen (adult nursing); Miss Henrietta Poole, Lady Superintendent, Adelaide Hospital, Dublin (adult nursing); Miss K. Hendie Close, Lady Superintendent, Hospital for Sick Children, Great Ormond-street (children's nursing); Miss Josephine de Pledge, Matron, Chelsea Infirmary (infirmary nursing); Miss Maud Mansel, Inspector, Queen Victoria's Jubilee Institute for Nurses (district nursing); Miss Edith Kirwan Ward (private nursing); Miss Sophie Cartwright, Sister-in-Charge, Gordon House Home Hospital (home nursing); Miss Annesley Kenealy, Lecturer to the National Health Society (sick dietary). As it is earnestly desired that the representation of British nursing appliances shall be as complete as possible, the subcommittee invite suggestions and exhibits from all parts of the country. Members of the subcommittee will be present at 53, Berners-street, W., every Monday until the end of July, from 5 P.M. to 6.30 P.M., to receive suggestions from all those nurses and others who are interested in this department of woman's work. Communications by letter to be addressed to Mrs. Bedford Fenwick, 20, Upper Wimpole-street, W.

MEDICAL NOTES IN PARLIAMENT.

The Vaccination Commission.

IN the House of Commons on Thursday, Mr. Summers asked the President of the Local Government Board whether it was his intention to propose legislation to give effect to the recommendations of the Royal Commission on Vaccination.—Mr. Channing asked the right hon. gentleman whether, in view of the fact that one of these recommendations was that vaccination prisoners should no longer be subject to the treatment of ordinary prisoners, he would assent to the second reading of the Prisons Acts Amendment Bill now before the House, and give to these prisoners the treatment of first-class misdemeanants.—Mr. Ritchie intimated that the Home Secretary would reply to the questions.—Mr. Matthews said that the Government had not yet had an opportunity of considering the report, and therefore were unable to make any statement on the subject.

The Coroners in Boroughs Bill.

When the order for the committee stage of this Bill is reached Sir Albert Rollit will move an instruction to the effect that the committee have power to extend the provisions of the Bill to the appointment of deputies of coroners in counties and as to the time of election.

Public Health Acts Amendment Bill.

This Bill was read a second time.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—8 P.M. Dr. Louis C. Parkes: Observations on the Seasonal Prevalence of Enteric Fever in London.

ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Mr. R. T. Lewis: On the Organs of Oviposition in certain Cattle Ticks.—Mr. E. M. Nelson: (1) The Penetrating Power of the Microscope; (2) The Rings and Brushes of Crystals.

SOCIETY OF ARTS.—8 P.M. Capt. W. De W. Abney: Colour Blindness.

Thursday, May 19.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.

ROYAL INSTITUTION.—3 P.M. Professor Dewar: The Chemistry of Gases.

LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Great Ormond-st.: 4 P.M., Dr. Cheadle: Intussusception, its Diagnosis and Treatment.—National Hospital for the Paralysed and Epileptic: 2 P.M., Dr. Buzzard: Cases in the Hospital.—London Throat Hospital, Gt. Portland-st.: 8 P.M., Mr. G. Stoker: Chronic Glandular Diseases of the Nose and Naso-pharynx.

SOCIETY OF ARTS.—8 P.M. Mr. J. A. Baines: The Administration of the Imperial Census of 1891 in India.

HARVEIAN SOCIETY.—8.30 P.M. Cases will be shown by Mr. Edmund Owen, Mr. Walsham, Mr. H. Work Dodd, Mr. Farmer, Dr. Sutherland, and others.

NEUROLOGICAL SOCIETY OF LONDON (20, Hanover-square).—8.30 P.M. Dr. Savill: Sequel to a case of Hysterical Rachialgia and Hypertonicity in a Man aged sixty.—Dr. Wiglesworth: Pachymeningitis Interna Hæmorrhagica.—Dr. Ferrier: (1) Tumour of Frontal Lobe; (2) Spinal Cord in Syringomyelia.—Dr. Taylor: (1) Spinal Cord in Syringomyelia; (2) Tumour of Spinal Cord with Ascending Degeneration.

Friday, May 20.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

LONDON POST-GRADUATE COURSE.—Hospital for Consumption, Brompton: 4 P.M., Dr. J. Kingston Fowler: Demonstration of Pulmonary Cases.—Bacteriological Laboratory, King's College: 11 A.M. to 1 P.M., Professor Crookshank: Anthrax (Gram's Method).—Charing-cross Medical School: 8 P.M., Dr. J. Braxton Hicks: Abdominal Tumours with Ascites.

ROYAL INSTITUTION.—9 P.M. Mr. J. Wilson Swan: Electro-Metallurgy.

Saturday, May 21.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

LONDON POST-GRADUATE COURSE.—Bethlem Hospital: 11 A.M., Dr. Percy Smith: Delusional Insanity.

ROYAL INSTITUTION.—3 P.M. Mr. E. Dannreuther: J. S. Bach's Chamber Music (with many Musical Illustrations).

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

DIRECT REPRESENTATION OF THE PROFESSION.

Dr. Rentoul.—The communication sent us is forcible. But the subject is not likely to be reopened in the Medical Council at present, only six months after the last debate. At some future time we shall be glad to insert such a letter.

Dr. Wm. Hy. Murray.—The solicitor is not responsible if he disclosed his principal.

Dr. Henry H. Rutherfoord.—The communication is receiving attention.

AN APPEAL.

To the Editors of THE LANCET.

SIRS,—An M.D., now advanced in years, has been reduced to want, mainly through ill-health. An opportunity offers of his taking up and establishing himself in a practice abroad, but he lacks means to meet the requirements of his outfit and travelling. May I, through your columns, ask the kindly aid of those who are able and willing to help an unfortunate but deserving brother?

I am, Sirs, yours faithfully,

Gloucester-place, W., May 12th, 1892. JOHN LOWE, M.D.

Subscriptions promised:—Dr. and Mrs. Lowe, £3.

Digitized by Google

"MEDICOS UNDER THE MICROSCOPE."

A RECENT victim of the writer in the *Gentlewoman*—who feels herself constrained by an overwhelming sense of duty to guide her sisters in London in the selection of their medical men, and who has come to regard her descriptions as certificates of merit which eminent practitioners have a right to expect—is Stephen Mackenzie, M.D., F.R.C.P. Dr. Mackenzie has our sympathy. Such notices can perhaps neither much help nor harm the gentlemen who are the subjects of them. But they do infinite harm to the profession by creating an impression that its members are responsible for them, and by teaching the public to look to newspapers for their guidance. It is to be hoped the College of Physicians will express itself in terms of unmistakable disapproval on this new and most undesirable form of journalism.

Dr. A. MacDonald (Cupar Fife).—We think that the assistant is only legally entitled to the remuneration for which he made engagement. Under the circumstances of the case, however, it would be kind and right to make him some adequate recompense for the extra work which he undertook.

Mr. B. M. Bond.—The communication will be dealt with in our next issue.

Hermes should consult his medical attendant.

THE TITLE OF DOCTOR.

To the Editors of THE LANCET.

SIRS,—With respect to the prefix "Dr." I myself always use it for all general practitioners and physicians. I do not consider whether the person is M.D., but simply use it to distinguish him as a member of the medical profession. If a man is M.D. he can put it on his plate, if he likes. Again, a man with an M.B. may not strictly call himself "Dr.," although by courtesy he is frequently so styled. The Scotch, Irish, and English (except London University) M.B.'s have only to wait a certain time after obtaining the M.B., then pay a fee, and send up a thesis. A man with three or four years' practice after leaving hospital ought not to find much difficulty in getting his M.D. in this way, and therefore the title of "Dr.," but a London University M.B. has a stiff examination to gain the title of M.D. and "Dr." When in practice it is more difficult to get any length of time to oneself, and therefore if you have not sufficient money to remain at hospital one or two years after the M.B., you may never get the M.D., and therefore the title "Dr." Is the London University M.B. as difficult (or more so) as the M.D. of any other university? On p. 989 of your issue of April 30th you say—"as matters stand, however, we cannot recommend self-respecting medical practitioners to lay claim to the prefix of 'Doctor' unless it is theirs by right of a university degree as well as 'the common consent of humanity.'" In this week's issue you speak of Dr. Wynn Westcott, Dr. Drew, Dr. Grierson Gledhill (a Bachelor of Medicine &c.). In the issue of April 23rd you speak of Dr. Thorne Thorne, and in that of April 16th of Dr. Meymott Tidy. Under the head of "Birmingham (from our own Correspondent)" this week, I see Dr. W. F. Wade and Dr. T. S. Wilson. The College of Physicians of London sent out cards this year for the lectures on Duodenal Digestion with the name of Dr. W. H. Allchin on them. They also give the title to other Fellows who are only M.B. Again, at the London hospitals (with medical schools attached) the names of physicians are always put up as "Dr.," whether they are M.B. or M.D.

I am, Sirs, yours faithfully,

May 9th, 1892. M.B., London, N.E.

*** Although graduates of a university who hold the M.D. degree are alone strictly entitled to the prefix of "Dr.," it is our custom to extend it as a matter of courtesy to possessors of the M.B. degree of all the universities.—ED. L.

Mr. E. Bowen (Monmouth).—A bond is legal. Whether the terms of a particular document are legal is another matter, on which our correspondent should consult his solicitor.

Dr. Mackay (Cambuslang) should communicate with the Honorary Secretaries of the Medical Defence Union at the Medical Institute, Birmingham.

Dr. Finzi.—The matter is under consideration.

"A MUSEUM OF CURIOSITIES."

To the Editors of THE LANCET.

SIRS,—The following case may prove of interest to some of your readers on account of the rarity of its occurrence.

On the 8th inst. Mrs. —— was delivered of a fully developed child that was found on examination to be a hermaphrodite, having labia in which I believe the testes were lodged, but in the interval between them there was no vaginal opening. The penis was not much larger than a clitoris, and the urethra opened on its under surface. The child had also a cleft soft palate, six fingers on each hand, six toes on the right foot, extreme talipes calcaneo-valgus on each side, and a depressed fissure over the sacral spine. The mother had previously been delivered of two children free from abnormalities.

I am, Sirs, yours faithfully,

Goswell-rd., E.C., May 9th, 1892. EVAN JONES, M.R.C.S., L.R.C.P.

THE ORCHARD ALUM SPRING.

Dr. Thresh of Chelmsford has communicated to us some interesting facts concerning the so-called alum spring near Orchard Farm, Buxton, Derbyshire, the water of which resembles in its nature that of the Flitwick Spring in Bedfordshire. The alum water in a wine-glass usually resembles pale sherry, and in Buxton has often been passed off as such upon the unwary victim of the practical joke. In larger bulk, as in the deep and quiet pools in the little mountain stream, it almost resembles blood. It has an acid taste and reaction, but contains no free acid. When heated to about 150° F. it becomes quite opaque from the separation of a basic ferric sulphate, but if allowed to evaporate on the water bath nearly to dryness the basic salt redissolves, and a yellow vitreous residue ultimately remains. The water after the deposition of the basic salt by heat becomes colourless. The amount of ferric sulphate (174·4 gr. per gallon) corresponds almost exactly with that found in the Flitwick chalybeate spring reported upon from THE LANCET laboratory on Oct. 24th last. The sulphate of alumina in the Buxton water, however, is twice and a half as great—no doubt a serious disadvantage from a therapeutical point of view. From Dr. Thresh's inquiries in and around Buxton it appears that half a century ago the alum water was held in considerable repute, and was fetched from the spring and employed for various purposes, chiefly as a tonic. It soon fell into disrepute, however, mainly on account of the constipation it produced. At the present time its virtues are vaunted amongst the labouring population of this portion of the High Peak as a vermifuge. Occasionally it is given to human beings, but more frequently it is administered to cattle. The animal is kept for some time without food or water, and is then allowed to drink as much of the "alum" water as it will.

Dr. T. Wittenberg (Nagy-Kanizsan, Austro-Hungary).—Our correspondent cannot do better than obtain the Parliamentary Blue-books on the subject, as they contain practically all that pertains to the water-supplies of England. The books may be had, we believe, of Messrs. Eyre and Spottiswoode, at the Sale Office, House of Lords. We are not acquainted with a work dealing comprehensively with all the subjects enumerated by our correspondent.

Dr. Sandell.—The most recent statistics will of course be found in the first and second reports of the Royal Commission on Vaccination. Our correspondent should consult Dr. MacVail's book entitled "Vaccination Vindicated," published by Messrs. Cassell and Co.

Mr. R. Dawson (Reigate) will perceive that we have dealt with the subject of his communication in another column.

THE EMPLOYMENT OF UNQUALIFIED ASSISTANTS.

To the Editors of THE LANCET.

SIRS,—Is it legal, and could I be visited by the General Medical Council with any penalty for employing an unqualified assistant to visit and attend midwifery?

I am, Sirs, yours truly,

A MEDICAL OFFICER OF A FRIENDLY ASSOCIATION.

May 7th, 1892.

*** It is difficult to say in any particular case what view the Medical Council would take of the employment of an unqualified assistant. The chief points in the resolutions and announcements of the Council on this subject are that for a practitioner to leave patients in the "sole" charge of an unqualified assistant, or to place such an assistant over a branch practice or in a separate house, or to let him act otherwise than under the direction, supervision, and responsibility of such practitioner, is to incur the risk of censure and punishment by the Council. The following resolution should especially be carefully noted:—"That the Council record on its minutes, for the information of those whom it may concern, that charges of gross misconduct in the employment of unqualified assistants and charges of dishonest collusion with unqualified practitioners in respect of the signing of medical certificates required for the purpose of any law or lawful contract are, if brought before the Council, regarded by the Council as charges of infamous conduct under the Medical Act."—ED. L.

Alpha.—A professional witness is entitled to second class railway fare and reasonable hotel expenses. The fee per diem varies from one to three guineas according to the discretion of the taxing master. The taxed costs are not open to inspection.

Mr. F. Guther Melville (Edinburgh).—Our correspondent is thanked for his information, of which, as he will perceive, we have availed ourselves in the present number.

A Country Surgeon.—We do not recollect the reference which our correspondent alludes to; but he might consult our advertising columns with advantage.

Mr. J. Carter should apply for information to the Agent-General, Colonial Office, Victoria-street, S.W.

Lecture
ON
THE CONCENTRATION OF POPULATION IN CITIES.

Delivered at University College, London, on Feb. 24th, 1892.

BY G. V. POORE, M.D., F.R.C.P.,

(Concluded from p. 1068.)

IT needs to be pointed out that the overcrowding of our cities, which is admittedly the greatest of all sanitary evils, is the direct result of sanitary legislation. When, some forty years since, it was recognised that water-carried sewage inevitably poisoned the wells, no attempt was made to protect the wells from pollution; but the surface wells were compulsorily closed, the inhabitants were sold in bondage to the water companies, and the houses were compelled to pollute our rivers. These measures have given a fatal facility for overcrowding, and wherever a line of sewers is taken the speculative builder follows; for, not being hampered by questions of water-supply or filth disposal (the sanitary authorities relieving him of all responsibilities in this matter), he is able to erect buildings without any curtilage, and of any height almost that he chooses. Be it observed that this state of things is not limited to London or the big towns. The notion that houses are as well without curtilage as with it has infected the country, as anybody may see for himself when travelling by railway. The train runs through miles of country, with scarcely a house to be seen; but when we stop at the developing district, growing up round the country station, we find the houses packed almost as closely as they are in the centres of towns. I have in my mind a village where land can be bought at very little above its agricultural value. This village has been selected by a railway company for the establishment of "works," and the company is erecting rows and rows of artisans' cottages with at most a few square feet of curtilage each. The onus of draining these cottages will ultimately be thrown on the local authority, with the additional onus, in a few years' time, of providing the inhabitants with allotments; and all the expense of this will fall upon the ratepayers as a whole. Clearly, the best place for an allotment is round the dwelling, and some compulsion should have been put upon this wealthy company to provide them. A couple of hundred acres of land (enough for 1000 cottages) might, I suspect, have been purchased in this particular spot for less than £10,000, and would have added £10 to the cost of each cottage. What is this to a rich company, especially if it be the means of increasing the health and contentment of their workpeople? Would it not be money well spent, and spent to the ultimate advantage of the shareholders? We have engendered a stingy habit of mind towards the question of space round houses, which almost amounts to a national insanity.

A country town which I know well, where 200 acres of land with a house and farm buildings, recently sold for £4000, has sanctioned the erection by a building society of 200 dwellings on six acres of land. This building estate will, if successful, have a population of 1000 persons, or nearly 170 to the acre, a degree of overcrowding about three times as great as that of the average of London. The building society will make a good profit, while the sanitary authority which sanctioned this scheme will ultimately have to deal with the infectious diseases of this crowded area, and will not only have to provide, at the expense of the ratepayers as a whole, for the safe bestowal of the filth from this area, but will also, possibly, be compelled to provide the tenants with allotments.

Can anything be worse from the hygienic point of view than the modern tenement house or monster hotel, where each floor ventilates into the floor above and the floor below, while the "lifts" effectually drive the air from one floor to another without renewing it? In such places, where hundreds live under a common roof, fresh air is impossible. Dr. Ogle, in his paper on "The Relation of Occupation to Disease and Mortality," read at the late Congress, pointed out that the mortality of hotel servants was higher than that of any other class, being nearly four times as great as that of the clergy, who enjoy the lowest degree of mortality. This high mortality is not to be wondered at, for the hotel servant never breathes fresh air, and lives day and night in an overcrowded dwelling redolent of humanity, dinners, gas, tobacco, and drains, one or all, most commonly all. Alcoholism may have something to do with this high mortality, but we must all admit that the unwholesome conditions of life are probably the main cause of the alcoholism. Drinking is said to be on the increase in this country, and I strongly suspect that it would be found to bear a very definite ratio to the overcrowding on space. The advantages of hotel life are many, and the charms of living in a pleasant community are very great. These charms have always been recognised, but when we contrast the "college," as seen at Oxford or Cambridge, with its ample area and the opportunities for society or seclusion at will, with the modern hotel, raised tier above tier, in which tranquillity and fresh air are alike unknown, it must be confessed that, æsthetically and hygienically, the mediæval architect was ahead of his successors. I have not in my mind merely those great hostelries in cities, where persons are content to jostle each other during a short paroxysm of business or pleasure; but I am thinking rather of establishments erected in health resorts and by the seaside, which have been designed for the reception of delicate persons and invalids, and which are well calculated, in my humble judgment, to bring chronic maladies to a termination.

Let us look at the question of overcrowding on space from an economic point of view. It is calculated that to raise the body vertically requires twenty times the force necessary for walking on the level, so that whether we mount stairs to the height of 100 feet or walk 2000 feet along the level the labour is the same. But I shall be told there are "lifts," and, that being the case, it becomes quicker and easier to move vertically than horizontally. It costs money to be carried, however, and a "lift" is a most extravagant machine, because it does not accommodate the force expended to the weight to be raised. In a report recently issued by the South London Electric Railway, I find it stated that the cost of working the lifts is 10 per cent. of the gross receipts! We are becoming alive to the fact that the fogs of London are getting more frequent and more virulent, in spite of the steady increase in the use of gas as a fuel. This is due to the overcrowding of houses and the multiplication of chimneys on a given area. In the country, and in most towns, the smoke is diluted to a point which practically gives us no trouble. It need hardly be said that a house of nine storeys will give off three times as much smoke as one of three storeys having the same area. In the centre of London we have been building enormous piles of offices and tenements, adding storeys to old houses, and putting buildings upon every garden and back yard, while at the same time the area of the city has enormously increased. What right have we to grumble at the increased density of the fogs? We have deliberately caused it, and neither Royal Commission, parliamentary committee, nor anthracite coal will put it right. Even though we got rid of the "blacks," we should still have the irritating invisible products of combustion—by far the most harmful of the elements of a fog—to deal with. We have made our bed, and we must lie upon it. The damage done to property by fogs, the extra cost of washing and painting entailed by living in the dirtiest capital city in the world, the serious loss of trade, the cost of using artificial light in the daytime, as well as the injury to health, must be all reckoned as among the penalties we pay for overcrowding. "Cleanliness is next to godliness," says the old adage, and we are bound to admit that the filthiness of the air of London is a not unimportant factor in causing the moral degradation in which not a few of the inhabitants are sunk.

One main object of overcrowding houses is the saving of time in the transaction of business, but there are limits which cannot be overstepped without defeating our object. The check put upon freedom of locomotion by overcrowding, and the time occupied in going from point to point, more than counterbalances the shortness of the distance which we have to travel, to say nothing of the fact, previously alluded to, that vertical movement requires twenty times the force of horizontal movement. In London rapid locomotion is getting daily more and more impossible, and there are so many vehicles and persons in the streets that

Digitized by Google

we are all in the way of each other. Our streets are always more or less blocked by building operations, which must be in proportion to the cubic contents of the buildings on a given area. Then, again, we have beneath our streets sewer pipes, water pipes, gas pipes, hydraulic power pipes, and pneumatic tubes, as well as wires for telegraphs, telephones, and electric lights. The necessity for interfering with these various subterranean arrangements in any one street must be largely proportionate to the number of dwellers whose front doors open into the street. These being almost unlimited, it follows that our streets instead of being only occasionally "up," as the phrase goes, are only occasionally "down." Again, the number of vehicles which stop at any given door is proportionate to the number of persons who live behind it. A set of "mansions" with 200 inhabitants may have scarcely more frontage than a modest house accommodating ten persons, but the vehicles stopping at them will be twenty times as many. It is the halting vehicles rather than the moving ones which offer the greatest obstacles to traffic. In civilised London we have very few back doors; our coals are shovelled in and our garbage hauled out under the dining-room windows; and these tedious operations, performed in the main thoroughfare, are in themselves great obstacles to traffic. The wear and tear of the streets is in proportion to the traffic, and in some of the leading thoroughfares the traffic has become so great that it is wonderful that any material can be found hard enough to stand it. These considerations make it clear, I think, that the increasing difficulties of locomotion in London are due to the overcrowding of houses on a given area.

From the æsthetic point of view the effects of overcrowding are disastrous. Proportion is one of the most important elements in architectural beauty, and few will be found to admire the Gargantuan architecture of the engineer-builder.

In spite of a somewhat dull uniformity, Regent-street still remains the finest street in London in virtue of its outline and proportions and the possibility of sunlight getting access to it. Contrast Regent-street with Northumberland-avenue, that drafty gloomy gorge of bricks and masonry in which the only really pretty building is the cabman's shelter at the end. It is mere waste to erect fine buildings in situations where they cannot be seen without effort. Every good building ought to have a proper "setting." How would Westminster Abbey look without its setting of greenery and turf? Can any building look really well without some verdure or floral decoration? Can any building that has them look really ill? In London our buildings are getting too high for their confined situations; they block out the sunlight, their many chimneys foul the air with soot, and, as a consequence, our palaces are grimy, and gardening, the most beautiful and the most health-giving of all arts, has become impossible. Wandering in the streets of London, and looking at the dim outline of our grimy public buildings looming through the mist, one is reminded of the lines from the opening of "Macbeth:"—

> Fair is foul, and foul is fair:
> Hover through the fog and filthy air.

When the air of a city gets so foul as to hinder and arrest vegetation, we are hygienically in a "parlous" state, as Touchstone would have said. Not only do the green leaves of plants absorb carbonic acid from, and give off oxygen to, the air, but their roots are no less useful in draining and purifying the soil upon which we live. We have heard a good deal about the dangers of an impure soil, and the advice with regard to it is invariably to put something which is impermeable, such as concrete or asphalte, to prevent the rising of possible impurities from the earth. This is analogous to putting dead bodies into impermeable coffins, whereby the danger of their decomposition is not prevented, but merely delayed. The only way to purify the soil is by cultivation, aeration, and the growth of plants. I believe that an evergreen creeper, such as ivy, does more to keep the foundations and walls of a house dry and pure than do any of the patent impermeable applications.

As London, in spite of all its "betterments," is getting steadily less habitable year by year, there is a growing tendency to sleep out of town and journey to and fro to business. Not more than 37,000 people sleep in that square mile which we call "the City"; but as more than 300,000 find permanent daily occupation there, it is obvious that there are some 260,000 daily workers who have to be transported to and from the suburbs. If we reckon cost and loss of time in transit, it will not be an extravagant estimate to suppose that this journeying involves a loss of one shilling per head per diem, or, collectively, £13,000 a day, £78,000 a week, and over £4,000,000 per annum. When a man lives out of town he becomes a slave to a railway company, he has to be punctual himself in order not to miss trains which are seldom punctual, and he finds out what it is to bear "the whips and scorns of time." As he wastes his time in being shuttled to and fro he must be queerly constituted if he does not wish for the good old times when it was possible to "live over the shop." Our modern facilities of communication cause us to be always in a hurry, and it is certainly a suggestive fact that having invested nearly £1,000,000,000 in railways, on which we go shrieking to and fro; having so perfected the penny post that it has become a veritable nuisance with its endless delivery of documents, which are mainly worthless waste paper in the form of advertisements; having annihilated time and space by the telegraph and telephone; and having abolished darkness by means of gas and electricity—there should arise an ominous cry for a limitation of the hours of labour and a demand to do by Act of Parliament that which, "in the good old days," the sun did for us.

There is yet another consideration which shows the cost of overcrowding houses. When growth occurs in an organised body, such as a tree or an animal, all parts increase *pari passu*, and there is no necessary loss of health or vigour. But in a city growth is more like an inflammatory swelling, the cells of the part increase, while there is no adequate increase of the channels which bring nutriment. Stasis is apt to occur, and unless relief be given by surgical means the death of the part will follow. The modern city is ever in need of surgical interference; new thoroughfares have to be cut in order to give relief to congested districts, and these operations can only be carried out by means of an expenditure of money which is simply appalling in amount. The attempt to improve the sanitary state of a city by a process of "Haussmannising" must be futile. If we make a fine boulevard through the slums the inhabitants are merely piled in heaps on either side; the width of the street is increased by increasing the overcrowding of inhabitants under a common roof, which is the greatest of all sanitary evils. Not long since I read a scheme (I think by Mr. Shaw Lefevre) for turning the Euston-road into a boulevard by appropriating all the front gardens and back yards, and erecting huge tenement houses on either side. No proposition could be worse from a sanitary point of view. It cannot be too earnestly insisted upon that the air of the grimiest back yard is better than that of any room, even though its (generally closed) windows command a view of a stately boulevard. The breathing of fresh air, so important to all, is doubly important to very young children. Children under four are too young to play in the streets; their mother's home duties are too arduous to allow her to take them to the park, and the little girl who might do so has been driven to school by the law. The result is that the little children have to breathe the fetid air of a small living room from week's end to week's end, instead of being able to play in a little yard, where the mother could watch them through the open door, as formerly was the case. The value of an open space is largely in proportion to its proximity to the dwelling. A little back yard or garden of one's own is worth infinitely more than Hyde Park a mile off, and the old graveyard converted into a garden a hundred yards down the street is far more precious to the poor town dweller than Epping Forest or Burnham Beeches.

This mention of disused graveyards leads me to say a few words on the disposal of the dead. Cremation is just now being strongly advocated, but, as I believe, on insufficient grounds, and for the following reasons:—1. Rational earth burial has never been shown to be productive of any evil, and the facts of bacteriology point to the conclusion that it is not a source of danger to the living. Even the scandalously irrational burial which has been permitted in the past has caused very little definite mischief, not even in those cases where the act of consecration has not been able to keep off the dangerous invasion of the graveyard by the railway contractor. 2. Cremation is wasteful, and involves a needless expenditure of fuel, and would help to still further pollute the air of our cities by products of combustion, always poisonous to breathe, and not always odourless. Dead bodies should be left to nitrify in the earth and provide nourishment for trees which, while affording us timber and firewood, would at the same time effectually cleanse the soil of its impurities and render it fit to be used for burial

Digitized by Google

a second time. The advocates of cremation say that this economic argument is false because the products of combustion are indestructible, and must ultimately go to nourish plants somewhere and somehow. This is doubtless true, and by parity of reasoning we might do well to throw our money into the street instead of paying it into the bank, and we might advocate the fertilising of the market gardens round London by setting fire to the manure in the London mews. 3. The necessity for burying the dead which hitherto has existed has had the indirect effect of separating the living and preventing to some extent the overcrowding of houses. If our cemeteries are to be replaced by furnaces with tall chimneys pouring noxious gases into the air, and if the ground which would be occupied by cemeteries is to be covered by houses, it is clear that we shall gain nothing from a sanitary point by the introduction of cremation. 4. Although I am a professor of medical jurisprudence, I think the objection that cremation will enable the poisoner to escape detection is a minor objection, though real.

The overcrowding of houses means loss of liberty, for the closer we crowd together the more likely we are to suffer from the sanitary negligence of others, and the more necessary does it become to regulate our actions by by-laws and Acts of Parliament. I need hardly insist on the fact, so ably enforced by Herbert Spencer, that personal liberty is necessary for social evolution, and that Acts of Parliament are evils only to be tolerated for the avoidance of greater evils. The growth of Acts of Parliament of late years, and the new offences which they constitute, was recently forcibly pointed out by the chief constable of Liverpool in a letter to *The Times*, in which he stated that in 1890 there were as many as 11,279 cases in Liverpool under the Education and Health Acts alone. Overcrowding has necessitated the compulsory notification of disease and the appointment of a crowd of inspectors, and there are those who wish to compel us to take out a licence for our houses, which is only to be given when they are fitted with the particular sanitary apparatus which happen to be in fashion. It is well to bear in mind that the overcrowding of which I am complaining is largely the result of compulsory Acts of Parliament which curtailed our liberty in the matter of water-supply and sewerage, while they gave to the speculative builder opportunities by which he has not failed to profit. When a couple of years since the influenza made its reappearance among us a distinguished engineer wrote to the papers with the kindly object of comforting us by the assurance that the perfection of our sanitation would certainly lessen the ravages of the epidemic. I need hardly say that my opinion was directly opposed to his, for influenza being an air-borne disease, and the overcrowding of houses and the fashion of many families living under a common roof having largely developed since its last appearance, it seemed probable that the epidemic would be more severe than formerly, and more difficult to eradicate.

Can nothing be done to check the overcrowding of houses and persons? Although we have passed many laws for the improvement of the public health, we have not sought as yet to put any very severe restraints on the builder and landowner, and we have not sought, as would seem but reasonable, to limit the number of inhabitants who may be accommodated on a given area of land. It is the object of all traders, whether they be public companies or individuals, to have the largest number of customers on the smallest possible area, and therefore any attempt at restriction cannot be popular. Neither would such restriction be popular with the sanitary authorities, who have to collect rates; for rateable value is unfortunately directly proportionate to the overcrowding of houses on a given area. We have borrowed large sums of money, and the rates have more than kept pace with our sanitary progress (the rates of my own house have risen more than 30 per cent. in the last twenty years), and as houses pay rates the authorities encourage building by every means in their power; they foster overcrowding and perhaps call it "betterment." Sanitary authorities are now being encouraged to embark in business as purveyors of water, gas, electricity, and locomotion; and as their success in business will depend upon the number of customers they can crowd into their respective areas, they are likely to be more biased than ever in favour of overcrowding.

One of the functions of a sanitary authority is to protect the public from the rapacity of public companies; and one would fear that the desire to make money out of the needs of the inhabitants must hamper the judgment and impartiality of the authority. This fashion of sanitary authorities to become purveyors must be regarded as an interesting socialistic experiment, but not one which is likely to conduce to the public health or public convenience. We have many sanitary laws, and the present does not seem the time to advocate a return to the liberty of the past. Unless the sanitary condition of our towns is to get steadily worse, we must have a law to prevent overcrowding. Such a law seems to me to be the necessary complement of all the others. We ought, I believe, to insist that every building shall have a minimum curtilage in proportion to its cubic contents, and it is evident that any such rule, to be of value, must be of universal application throughout the country. Such a rule, I shall be told, is impossible because of the high price of building land in cities. To this objection my answer is that the exorbitant price of building land is the result of the absence of any such rule, for the value of building land is, *cæteris paribus*, proportionate to the number of inhabitants it will accommodate; and if the accommodation of a given area is to be unlimited, the price of land will be almost unlimited also. It is evident that any rule for making the minimum curtilage proportionate to the cubic contents must not be too exacting, and must be very simple and capable of universal application. Suppose we were to say that the curtilage of a building shall in no case be less than an area expressed by a figure representing 1 per cent. of the cubic contents of the building. This is certainly a very modest demand. Let us see how it would work. By such a rule as this a building like the Masonic Hall at Chicago, which is 114 ft. × 117 ft. × 265 ft., and which (to take round numbers for simplicity) contains about 3,500,000 cubic feet, would require 35,000 square feet of curtilage, and since the area of the building itself is 13,000 square feet, the size of the entire plot of ground which it would require would be 48,000 square feet, or about an acre and one-eighth. Assuming that this building can accommodate 1000 persons (probably a low estimate), it is evident that, even with the compulsory curtilage which I suggest, we should still have a condition of overcrowding on space which must be regarded as indefensible.

The average London dwelling house, which has about twenty feet frontage with a height of sixty feet and a depth of fifty feet, contains 60,000 cubic feet, and ought, according to the rule I have suggested, to have a minimum curtilage of 600 feet—i.e., a back yard as wide as the house, and thirty feet long. Such a house would accommodate about ten persons, and would occupy 1600 square feet of ground, or, with its necessary proportion of street, 2200 square feet, or, as near as may be, the twentieth of an acre. Even under these circumstances we should have 200 inhabitants to the acre, which is a number certainly largely in excess of what ought to be allowed. It is evident that unless we know the maximum number of inhabitants which is to be permitted on a given area, it is impossible to make any reliable calculations as to water-supply and sewage disposal. It does not seem to me more unreasonable to set a limit to overcrowding houses on a given area than it is to require a definite cubic space for the inhabitants of common lodging houses. This rule could not, of course, be applied to existing houses, but the cubic contents of such houses or of houses built to replace them ought not to be suffered to be increased unless this rule or something like it be observed. If we allow the cubic contents of buildings to be indefinitely increased regardless of the question of curtilage, as is being done in every part of London, it is certain that the condition of public health must steadily deteriorate. To imagine otherwise would be to give the lie to those elementary facts of physiology and hygiene which are universally admitted. To purchase plots of vacant ground at exorbitant rates, and miscall them "lungs," is no true remedy for overcrowding. The only true remedy is to have the open ground dovetailing with the houses. Let us also remember that overcrowding in the daytime is no less harmful than overcrowding at night. The citizens of London have seldom had an eye to anything except immediate profit. They allowed Moorfields and the Drapers' garden to be sold for enormous sums, without a thought for the health of the thousands of young men and women who daily toil in this overcrowded spot; and they have taken no heed of the Registrar-General's returns, which are telling them that the death-rate at the prime of life (i.e., between the ages

Digitized by Google

of thirty-five and sixty-five), which has been steadily rising for the whole kingdom, is nearly 70 per cent. higher in London than it is in the best country districts. No regulation other than the insistance upon a proportion being observed between cubic contents and curtilage would serve to check overcrowding. An arbitrary rule to limit the height of buildings is not sufficient, because if the builder be not allowed to soar he will commence to burrow as he is doing in Chicago, and as he has done for many years past in London. A crying need in London is for back doors and back streets between the houses for delivering goods, and beneath which could be laid the various subterranean pipes and wires, the repairing of which is so frequent a cause of blocking the main thoroughfares. A system of back streets would do more to facilitate the traffic of the thoroughfares than a similar addition made to the width of the main streets.

I am told that the views I have been laying before you are impracticable because overcrowding is necessary for business, and it is asserted by some that the commercial prosperity of this country and America is largely due to the fact that the business men are content to literally crawl over each other in an ecstasy of frenzied competition which is making existence a burden. I feel convinced, however, that this question of overcrowding on space is one which must be dealt with in the future in no niggardly spirit, and that our national and commercial prosperity very largely depend on our willingness and ability to face it. The inadequate housing of the working classes has, I believe, more to do with their chronic discontent than is generally supposed. A real "home," be it remembered, is a very different thing from a room in a barrack. A home that is clean and bright and beautiful, the beauties of which have increased year by year under the owner's fostering care, where the children have space to grow up healthily, and where there is some escape from the dirt and din of the workshop—a home in which it is possible to take a pride, and which is a source of daily pleasure—is something which a man will weigh carefully in the balance before he lightly determines on throwing up his employment. A decent home without sufficient space is impossible, and the sooner that great industrial companies and employers of labour grasp this idea the better. That the labouring classes are beginning to grasp it is shown by the recent agitation in the East-end of London against replacing the two-storeyed houses by industrial barracks. The fashion of piling people in heaps, and offering them libraries and bagatelle tables as a compensation must come to an end, and I look forward hopefully to the working of the Allotment Act, especially when it is recognised that the proper place for the allotment is round the house. Thirty perches (rather less than a fifth of an acre) is the maximum amount of garden which a man can cultivate at his leisure, and it is the little bit of garden which converts a dwelling into a home, which provides a delightful occupation for a man's leisure hours, which freshens the air round the dwelling, which keeps a man from the tavern and the sixpenny betting hell, and which is capable of turning all the refuse of the house into profitable garden produce. Not much improvement is to be looked for until the conscience of the educated and upper classes has been roused. As long as persons in high position are content to leave their broad acres and swelter for the season in highly decorated "bijou residences," where the servants are poked away underground or in miserable attics, not much improvement can be expected. Many of the persons who come to London for the season are philanthropists whose hearts "bleed" for the miseries of the East-end. These people forget that when they come to town they make it necessary for humbler people who minister to their wants to come to London also; and that, if they who are wealthy are content to live on a very insufficient area, their poor dependents must necessarily be packed together in great discomfort and at the cost of their physical and moral wellbeing. Let those who are sorry for the state of overcrowding in cities stop out of them, and spend their incomes in the country. If they can succeed in making those who live round them in the country happy and contented, and thus check the rush for the towns, they will do infinitely more good than by subscribing to city missions or "People's Palaces." Unless we can succeed in checking the overcrowding of cities by some such regulation as that which I have suggested, I believe that all the money we have spent and are spending on so-called sanitary improvements to be money thrown away, and that, in so far as modern hygienic methods have enables people to live closer packed than heretofore, I believe they have worked mischief rather than good. Those who have the control of developing districts will do well to keep them as rural as possible, and encourage private gardens by every means in their power. The house ought to be taxed in proportion to its size, and not the garden round it; for a garden is a great boon in a town, even to those who do not own it, because it serves to keep the dwelling-houses asunder. A person who owns a garden may, if he be so minded, be quite independent of the sanitary authority; and a wise sanitary authority will do well, by a remission of taxation, to encourage him by every means in its power. So long as sanitary authorities are content merely to encourage the jerry builder by clearing up his messes and making good his deficiences, not much improvement is to be expected. Such policy may be "good for trade," but it is not good for the public health.

Finally, one hopes that it may be increasingly possible for a man to own his dwelling and the ground around it, and that the transfer of land may be much facilitated. I am not going to embark on a discussion as to the relative advantages of large and small holdings; but I would merely remark that it is certain that no one is so likely to do justice to the land and to improve it as the absolute owner, whether he own a thousand acres or only one. If a man owns a bit of land, be it farm or garden, he is bound in self-defence to make the best of it, and he can have no object in quarrelling with, cheating, or shooting his landlord. This last is a point which political economists not unfrequently neglect. We are often told that large holdings are more economical than small ones, and it is pointed out that on the farms of our large proprietors the yield per acre is greater than the yield on the land of the peasant proprietors of France or elsewhere. Our big farmers, however, have not of late years grown rich, and I do not think that free trade is the sole cause of this. Is it not possible to farm too high for profit? We may drive a steamship ten knots an hour at a profit, but lose by attempting to get fifteen knots out of her. So I fancy that much of the profit of farming is frittered away in a lavish expenditure on artificial fertilisers, in the desire to get excessive crops. Small holdings and gardens and what I have called the dovetailing of the houses and the land have two advantages which are often lost sight of. The first is that the producer and consumer are largely identical, so that the middleman and free trade are alike powerless to do him harm. The second is that all the refuse of the house is available for the land, and in proportion to its amount is the expense of buying "artificials" and the risk of keeping stock done away with. The key to good agriculture is thrift, and no arrangement more thrifty than that which I have indicated can be conceived. The key to good sanitation is agriculture, and therefore no effort should be spared to maintain a rural element even in our great industrial centres.

A Clinical Lecture

ON

THE TREATMENT OF SPINAL AND OTHER TUBERCULAR ABSCESSES.

Delivered at the London Hospital,

BY FREDERICK TREVES, F.R.C.S.ENG.,

SURGEON TO THE HOSPITAL.

GENTLEMEN,—Among the advances which may be claimed for surgery in recent years must be placed an improved treatment of abscess, and especially of that chronic form of abscess which depends upon tubercular disease. For a considerable period the whole art and science of the treatment of suppurating cavities was embraced by the advice, "*Ubi pus, ibi evacua.*" Into the abscess a very tardy and very small incision was made. The position of the cut was unimportant. If carried out with a dirty lancet it mattered little. Following upon the operation came a squalid and unwholesome period of poultices and foul dressings, and after that, as a rule, hectic and the burrowing of pus. The

Digitized by Google

subjects of large abscess who escaped death in those days had not to thank the surgery of the time. The introduction of the principles of drainage and the teaching of antiseptic surgery brought about a revolution in the treatment of the abscess. The incision made was free, and was so placed as to allow of the readiest escape of the matter. Every step was taken to keep the abscess cavity not only empty, but also surgically clean. The treatment involved considerable trouble, but it was attended by excellent results. In dealing with minor abscesses—especially in children—little fault can be found with this method even at the present time. In order to ensure the most complete and ready evacuation of the pus in psoas abscess I urged—in a paper read before the Royal Medical and Chirurgical Society on Jan. 8th, 1884—that such abscesses should be opened from the loin. I described the steps of an operation whereby the psoas muscle could be safely reached through an incision at the outer margin of the erector spinæ. The wound thus made opened the abscess at its most dependent point, and evacuated the pus by the most direct route. It enabled the surgeon also to examine the vertebræ in the lumbar region, and in children and slender adults such an examination is readily carried out. In the first case recorded I removed from the spine a large sequestrum involving the greater part of the body of the first lumbar vertebra. The patient was a woman aged twenty-one, in Mary ward. Since then there have been many cases in my wards in which the simple draining and frequent irrigation of a psoas abscess have been followed by cure, but I would have you note that in these successful cases the patients were young children.

The lumbar incision is not possible when such deformity exists as brings the ribs close to the iliac crest, nor is it easy in the person of a very tall and fleshy adult. The invention of the sharp spoon and the method of removing chronic inflammatory deposits by scraping introduced a new element into the treatment of tubercular abscesses. Mr. Barker and Mr. Bilton Pollard have reported cases of excision of the hip in which the inflammatory tissue was removed by scraping and flushing with hot water, and in which primary healing followed without the intervention of a drainage-tube.[1] These cases are very striking and remarkable, and afford a strange contrast to the results obtained in the past.

It is difficult to trace the origin of the method of treating tubercular abscesses by incision and scraping, followed by closure of the wound without drainage, but the procedure is very conspicuously associated with the name of M. Trélat, who carried out a large number of these operations, for the most part in small abscesses, in 1887.[2] Side by side with this plan of dealing with the chronic abscess comes the method by repeated aspiration, followed by the injection of a solution of iodoform. This procedure would appear to have been originated by Verneuil, and has been very extensively employed. Numerous examples of cure by this method have been reported. Such examples disarm criticism, but on theoretical grounds it is impossible not to urge certain objections against the procedure. In the abscesses we are now dealing with there is a considerable quantity of semi-solid matter which cannot be removed by the aspirator. This and the abscess "sac" are left behind, and would appear to provide the very material necessary for the foundation at a later period of a "residual abscess." In dealing with all tubercular affections a very free removal would appear to be of primary importance.

The operation.—I might now describe the particular method of treatment by scraping I have myself adopted, and will illustrate it by a series of examples. Certain of these cases you have seen for yourselves in the wards during the last few months. An incision is made into the abscess at the most convenient spot, and, whenever possible, at the most dependent point. It should be so placed as to command all parts of the abscess, and to allow of access to its remotest quarters. It must be made through perfectly sound skin. The pus is allowed to escape, and the abscess cavity is then washed out with a hot solution of corrosive sublimate of the strength of 1 in 5000. For this purpose a Leiter's irrigator of the largest size, and suspended at a height of twelve feet, is convenient. Many gallons of the solution are required. When the fluid returns clear the fingers are introduced into the cavity, and the caseous semi-solid matter which exists in such quantity in these abscesses, and which is not wholly removed by flushing, can be dislodged. By means of the fingers also septa in the cavity may be broken down, diverticula may be opened up, and by the aid of the finger nails a considerable quantity of the smooth slimy lining membrane of the abscess may be removed. Repeatedly the cavity is flushed out with the warm solution. The lining wall of the abscess is now carefully and thoroughly scraped with a Volkmann's spoon until the whole surface has been laid bare. Now and again the process is interrupted to allow of the cavity being once more flushed out so as to remove such débris as may have collected. The simple Volkmann's spoon has appeared to me to be a more convenient instrument than the ingenious flushing gouge invented by Mr. Barker and used by him with such pronounced success. The sharp spoon is more readily manipulated and is more completely under control, and in dealing with thin-walled abscesses within the abdomen this matter must be regarded as of vital importance. The rushing of water during the process of scraping with the gouge is a little confusing, and is apt to interfere with the precision of one's movements. In dealing with tubercular joints, Mr. Barker's instrument leaves little to be desired. After the scraping and flushing have been persevered with until all the lining membrane appears to have been removed there comes what I believe to be the most important part of the operation—the rubbing of the abscess wall with sponges, and the thorough drying of the cavity. I use small hard Turkey sponges in holders. The holders are shaped like slender pressure forceps of the largest kind, and are about a foot in length. By means of the sponges the whole of the abscess wall is vigorously rubbed, and it is surprising what a quantity of inflammatory material in the form of the slimy lining membrane, and even cheesy pus, comes away upon these sponges. It is at once made evident that much that it is necessary to detach may escape the sharp spoon, and that the stream of water will only remove such matter as is quite free. The sponging process is tedious, but it leaves the cavity practically dry. The abscess cavity is now a raw space almost comparable to that which would be left after the removal of a large and adherent tumour. If the proceeding have been successful, the great space should be free of all altered pus, and bared of all the lining membrane. In deep abscesses it cannot always be demonstrated that this has been done, but no pains should be spared in endeavouring to effect it. The operation may occupy more than sixty minutes when deeply placed abscesses in adults are being dealt with. The oozing of blood, which is at first considerable, soon ceases, and the last sponge used should be withdrawn practically unsoiled. The incision is now closed entirely with silkworm gut sutures. No antiseptic is introduced into the abscess cavity, and of course no drainage-tube is employed. A dressing of Tillmanns' linen or cotton-wool dusted with iodoform is applied, and, whenever possible, I endeavour to obliterate the abscess cavity to some extent by suitably placed pads and pressure.

The value of the method is illustrated by the cases which are about to be described. In the simplest of these the cure is rapid and complete; the wound heals by first intention; there is no pain and no rise of temperature; the abscess is as completely removed as is a dermoid cyst which has been dissected out. A sufficient time has to elapse to allow of sound healing, and after that the patient may be considered to be well. Examples of such an issue are afforded by Cases 1, 2, and 3. It will be noticed that two of these are instances of large abscesses in patients of seventeen years of age. These are cases which test the value of any measure of treatment. Abscesses in young children often do so well after even the most rudimentary treatment that they can hardly be quoted as demonstrating the superiority of a particular method. Large chronic abscesses in adults are, however, not so amenable to the simpler surgical measures. Had Cases 2 and 3 been treated merely by incision and drainage, there would have been great risk of tedious suppuration, of long confinement in bed, of hectic fever, of a wearisome sinus, and of a greater or lesser degree of exhaustion. As it was, the whole trouble healed up practically under one dressing.

An abscess which has been already opened by a simple incision, and which has become utterly septic, may be treated in the manner described, and may yield an excellent result. This is illustrated by Case 4, in the person of a boy aged fifteen.

In dealing with spinal abscesses certain difficulties arise,

Digitized by Google

the chief of which depend upon obstacles in the way of the complete evacuation of the abscess and the complete removal of its lining membrane. The depth of the cavity, its great length, and its position within the abdomen (assuming it to have followed the psoas muscle), place difficulties in the way of the treatment I have detailed. In the cases described two of the patients were children and two were adults. In the former the operation was carried out a little late. In one of these the skin gave way, and an open wound resulted. It must be noted, however, how the scraping and irrigation had affected the issue. The cavity seems to have closed almost from the first. It contained no material capable of developing a rapid decomposition. There was no rise of temperature, and the resulting sinus was not long in closing. Cases 7 and 8 (adults) call for little comment. In such examples of abscess, it must be remembered that another element assists in the healing of the suppurating cavity, and that is the long confinement in bed, rendered necessary by the disease in or about the vertebral column. In the last recorded case the abscess was opened twice. It would have been better if the second incision could have been replaced by aspiration and the injection of a solution of iodoform. As the greater part at least of the curdy contents and the thick lining membrane had been already removed, the condition of the cavity was favourable for such treatment. The abscess, however, was comparatively small, and was so deeply placed near the median line as to render aspiration distinctly dangerous. I had already ascertained that its anterior wall was thin, and was in immediate relation with the peritoneum and non-adherent intestine. I think, however, that this should be the treatment aimed at whenever aspiration may be attempted with safety, and the surgeon is satisfied that the abscess cavity has been thoroughly evacuated at the first operation.

CASE 1. *Femoral abscess.*—A girl aged five was admitted on Sept. 19th, 1891, with a very large and deeply placed abscess at the upper and inner part of the right thigh. The child had been lame in the right hip for several months. There was a history of scrofulous disease in the family. On Sept. 26th the abscess was opened by a two-inch incision, and treated as above described. The abscess cavity reached from Poupart's ligament to the middle of the thigh, and was subfascial; it healed by first intention under one dressing. There was no rise of temperature. She left the hospital in thirty-four days, free from lameness or any other symptom.

CASE 2. *Iliac abscess.*—A young woman aged seventeen, anæmic and unhealthy-looking, was admitted on Sept. 24th, 1891, with a tumour in the left iliac fossa, which had at one time been considered to be a dermoid cyst of the ovary. The patient had had strumous glands in the neck; one sister had such glands in the neck now. Her father's brother died of phthisis. The swelling had been noticed eight months; it reached to the margins of the ribs above and to the median line of the abdomen on the inner side. Below it filled the iliac fossa, and extended down the thigh for eight inches below Poupart's ligament. No pain or tenderness was complained of. Menstruation had been absent for five months; spine apparently sound; temperature between 99° and 100·6°; abscess evacuated on Oct. 5th by a three-inch incision close to the anterior superior iliac spine; forty-three ounces of thick pus evacuated with much curdy matter; cavity treated as above described; healed by first intention under one dressing; temperature remained normal. She left the hospital on the twentieth day sound and well. The whole of the iliac fossa was now resonant on percussion, and no trace of the abscess sac could be discovered.

CASE 3. *Iliac abscess.*—A young man aged seventeen, tall and delicate-looking, of a tubercular family, was admitted on Nov. 16th, 1891. An abscess extended from the left iliac fossa on a level with the summit of the iliac crest down the thigh for a distance of two inches and a half below Poupart's ligament. There was no evidence of disease either in the hip-joint or in the spine. The patient had, however, been confined in bed for a period of five months. The abscess was opened on Nov. 20th, just below Poupart's ligament. More than thirty ounces of pus were evacuated and much semi-solid matter was scraped away. The cavity was treated in the manner above described. The wound healed by first intention under one dressing. There was no rise of temperature. The patient, who was enfeebled by long confinement in bed, got up on the twenty-first day, and left the hospital on the forty-second day. Of the abscess sac no trace could be discovered.

CASE 4. *Septic abscess about the hip.*—A boy aged fifteen was admitted on Nov. 16th, 1891. Symptoms of hip disease began two years ago. These improved with rest, but returned as the patient attempted to move again. He had been confined to bed since July last. In that month an abscess was discovered on the upper and outer part of the thigh. This was opened by a medical man by means of a small incision less than one inch in length, and was not drained. Pus had discharged ever since—i.e., for four months. Just before admission the little wound had closed. The patient presented the symptoms of hectic, and was much emaciated. He was miserably ill, and had a troublesome cough. A large abscess with thin walls was evident on the outer side of the thigh. It was opened on Nov. 21st by a six-inch incision. Two pints of very foul pus were let out. The abscess cavity was treated in the manner above described, and the wound was closed. On the eleventh day the thinned skin gave way at one point, but the escape of matter was small, and it was evident that the great abscess cavity was practically closed. There was no rise of temperature, which ran to between normal and 99° a few days after the operation. A small drainage-tube was inserted into the sinus thus produced, and passed in one inch and a half. The discharge soon ceased, and the tube was removed. The patient was up on Jan. 1st, and a few days later the little sinus was soundly healed. On Jan. 20th he was able to move about on crutches, and on the 22nd he left the hospital greatly improved in health and appearance, and with no local symptoms except a stiff hip-joint.

CASE 5. *Spinal abscess in a child.*—A little girl aged seven years was admitted on Feb. 6th, 1890, with a large psoas abscess on the right side actually pointing below Poupart's ligament. There was caries in the lower dorsal region. The thigh was much flexed. The abscess was opened from the loin on Feb. 14th by the incision already recommended, and the cavity was treated in the manner above described. A pint and a half of curdy pus was evacuated. The incision was then closed. In the course of a few days the thin and reddened skin in the groin, where the abscess was pointing, gave way. Later on I reopened the wound in the loin, to allow of more free washing out of the cavity, which soon assumed the dimensions of a small sinus. This in due course healed soundly, and the child's recovery was complete. She was kept in bed several weeks as a precaution, and was discharged cured on June 22nd.

CASE 6. *Spinal abscess in a boy of thirteen.*—The patient was admitted on Feb. 6th, 1891. Several members of his family had died of phthisis. The patient was very ill; his temperature was 103°, and he complained of great pain in the back. A lumbar abscess, dependent upon disease in the lower dorsal spine, was evident. It was incised, irrigated, and scraped on Feb. 14th. Up to this time the temperature had varied between 100° and 103°. Twenty ounces of pus were let out. The wound was then closed. The temperature fell next day to 99°, and soon became normal. On Feb. 19th a fulness appeared at the site of the wound. The wound was opened, and a little pus escaped. No drain was needed, so slight was the discharge. This little sinus was entirely closed on March 18th. After a few more weeks' rest the patient was allowed to leave the hospital on April 7th, and was then quite sound.

CASE 7. *Spinal abscess in an adult; paraplegia.*—The patient, a gentleman aged twenty-two, came under my notice on June 20th, 1890. Symptoms of spinal caries had appeared without apparent cause nine months previously. Complete paraplegia with loss of power over the bladder and rectum had existed since Feb 20th. There was evidence of disease in the second and third lumbar vertebræ. Some swelling in the right psoas muscle was detected, but it was not sufficiently definite to demand treatment. The patient was kept rigidly in the recumbent position. By January, 1891, the paraplegia was much better, but the condition of the bladder remained unaltered. A psoas abscess on the right side was now evident. It was near to the median line. The patient was a man of exceptional stature, and I came to the conclusion that the abscess could not be reached through the loin. It was opened from the iliac region, and was reached behind the peritoneum with much difficulty. The amount of pus which escaped was estimated at twenty-five ounces. The cavity was dealt with in the

Digitized by Google

manner already described. Its great depth rendered its complete erasion difficult. The wound was closed. In three weeks' time some swelling was noticed under the firmly healed cicatrix. This was cut into, and a little pus—an ounce or less—escaped. The resulting sinus healed without difficulty. The patient was still kept in the recumbent position. He was allowed to get up on July 20th, 1891, with a spinal jacket on. He had by this time entirely recovered from the paralysis of the lower limbs and the bladder. He spent the rest of the summer at the seaside, and in the late autumn went abroad. No trace of the abscess sac could be discovered, and his recovery was in every respect complete.

CASE 8. *Spinal abscess in an adult.*—A gentleman aged twenty-eight had complained of spinal symptoms since 1886. In this year deformity and rigidity of the lumbar spine were noticed, the most prominent spinal process being that of the first lumbar vertebra. The pain in the back became more severe and spinal supports were worn. With the aid of these the patient, who was a very active man, was enabled to attend to his profession. I saw him in January, 1890. He then had a large psoas abscess on the right side; no paraplegia or other signs of paralysis. On Feb. 9th, 1890, I opened the abscess through the loin incision. It was reached with difficulty, owing to its having avoided the lumbar region; a pint and a half of very thick pus was evacuated. I was able to examine with the finger the bodies of the lumbar vertebræ, and found them free from any active disease. They had, however, been considerably deformed by old caries. The abscess cavity was treated in the manner already described, and the wound was closed. The patient was kept absolutely rigid upon the back. Six weeks after this operation I discovered once more a fulness in the right psoas, together with distinct fluctuation. The swelling was close to the median line. I was convinced that aspiration would be dangerous. The pus could not be reached from the front without penetrating the peritoneum, and the depth of the collection from the loin rendered a determined puncture in that direction distinctly hazardous. I once more opened the abscess from the loin, cutting through the firmly healed scar. Owing to its depth and comparatively small size I had very considerable difficulty in reaching the collection. Only six ounces were evacuated, which were composed of thin laudable pus, serum, and blood. The first abscess had contained much curdy or semi-caseous matter, but there was none in this. The abscess was treated in the same manner as before, and the wound was once more closed. It healed soundly by first intention. The patient was kept upon his back until June 1st, 1891, when he was allowed to get up with a spinal jacket. For some months after the second operation the site of the abscess sac could be made out on palpation, but no fluctuation was ever discovered. In due course all trace of the sac disappeared, and the patient's recovery has been in every way complete.

ON "POST-EXPIRATION" FRICTION SOUND.

BY J. WALLACE ANDERSON, M.D.,
LECTURER ON MEDICINE, QUEEN MARGARET COLLEGE, GLASGOW.

A PHYSICAL SIGN of pulmonary or cardiac disease which has escaped, or appears to have escaped, the observation of clinical investigators can hardly be one that is either very evident or very common; and there is this unfortunate circumstance connected with any stethoscopic sign, such as the one to which I am about to refer, that it is essentially a matter of personal observation and capable of demonstration to so very limited a degree. I feel therefore, and have felt from the first, at a disadvantage in dealing with a question of this kind; but I can say at the same time that it has made me the more severely critical of my own observation, and slow to proclaim the result. Indeed it is chiefly with the hope of eliciting corroboration that I do this now, and I am far from thinking that there is anything of essential value in the point that I am about to notice, or that I have anything in the way of a discovery to bring before the profession. I only say that I cannot find any reference in any text-book with which I am acquainted to this "post-expiration" friction sound, as I would call it. I have no record of when my attention was first directed to this particular form of friction sound, and for that reason I shall be more precise in narrating how I referred to it when I noted it for the first time in my ward journal.

J. C——, a miner aged forty-seven, was admitted to Ward 12 of the Glasgow Royal Infirmary, under my care, on Sept. 2nd, 1887, suffering, as was said, from "bronchitis." The report of my then resident physician (Dr. Ord) states that the patient had to give up his work a fortnight previous to admission on account of a pain in the left side attended with difficulty of breathing, severe cough, and very little expectoration. On physical examination he found that there was some slight dulness at the base of the left lung posteriorly, and that a little higher up friction sound was heard. There was no evidence of disease of any other organ. On the following morning I detected the friction under the left scapula, and had my attention at once arrested by the peculiar short jerky rub that succeeded each expiration—i.e., it followed the completed expiration movement of the chest wall. The peculiarity was quite distinct, and was easily recognised by my assistant and the senior students. I spoke of its being no novelty to myself, although they would not find it referred to in their text-books, and added that I would be glad to hear from any of them, should they happen to meet with it in their practice. For the next few days the phenomenon was freely discussed by us, and I pointed out that it seemed as if the one roughened pleural surface was caught and held by the other, and only set free with a sudden jerk when expiration was completed; or else that some further movement of the visceral pleural surface occurred after the costal expiratory movement had ceased. The friction sound and the other symptoms and signs of pleurisy gradually passed off; there was nothing else of special interest in the case, and the patient was dismissed well on Oct. 7th. The matter not being of any great practical importance, I determined that I would wait for one more example of the phenomenon before putting it on record, and I do not think I shall be charged with a too lively imagination when I say that I did not hear it again unmistakably until a few weeks ago, although I have had many opportunities of listening to friction sound since then, and of studying it quietly and at leisure in hospital. I shall confine myself almost entirely to the relevant features of the case.

P. D——, twenty-seven, labourer, was admitted on Jan. 19th, 1892, to Ward 7 of the Royal Infirmary, complaining of "bronchitis" of two weeks' duration. He was very ill and weak on admission, and only a partial physical examination of his chest was made. Under Jan. 22nd there is a note of a comparatively rapid examination by myself—rapid because the patient was still weak and very short of breath. I found that there was little respiratory murmur to be heard over the lower half of both lungs posteriorly, and what was heard was accompanied by fine mucous râles, with here and there a faint cooing râle. I concluded that the patient was suffering from a diffused broncho-pneumonia. Again, on January 25th, I made a pretty full note, but will only quote the closing paragraph: "Dr. Anderson particularly notes at various points over the lower right lung posteriorly a râle or sound of some kind that is certainly 'post expiratory'; that is, it occurs after expiration movement of the chest wall has ceased—a shuffling or rubbing-like sound; but the character of the sound itself is not such as to point quite definitely to friction, though suggestive of it. To this extent the sound is corroborated by Dr. Scott Macgregor and Dr. J. A. Wilson. Dr. Anderson hears it again by immediate auscultation." This is the note as it stands. I meant that without being committed to the pathological explanation, but considered simply as a physical phenomenon, my tutorial assistant and my house physician were quite certain that the sound occurred *after* each completed expiratory movement. This friction-like sound was, on this first occasion of its being heard, concealed to some extent by other râles, and I was anxious to exercise every care in the investigation. But on the next day (Jan. 26th) there is the following note:—"To-day Dr. Anderson observed that the râles had cleared up considerably, and that the sound which yesterday he heard through these râles, and thought was pleuritic friction, comes out now quite distinctly, and there is no doubt in his mind as to its being friction occuring after expiration." On the 27th I note that "the post-expiratory phenomenon has quite disappeared," and, beyond the suspicion of its

Digitized by Google

being heard once on the left side, there is no further reference to it. The notes that follow deal entirely with the increasing gravity of the case from the advancing implication of the lungs themselves. The patient died on Jan. 31st.

A post-mortem examination was made on Feb. 3rd by Dr. Lindsay Steven, pathologist to the infirmary. His summary of the lung condition is: "Emphysema; right pleurisy; left pleuro-pneumonia; bronchitis;" and he goes on to say—"the right lung is extremely emphysematous, and almost its whole pleural surface covered with a very slight fibrinous exudation. The bronchial mucous membrane is intensely congested, and muco-purulent material issues from the fine branches. At the base of the left lung there is a pretty copious recent fibrinous exudation corresponding in extent to an area of solidified lung tissue. In the lower lobe the solidified lung sinks in water, and presents the characters of red hepatisation. It is obvious that the patient has been developing a pleuro-pneumonia in the left lung; the bronchial mucous membrane is also extremely congested." I was present at the post-mortem examination, and saw no such roughening of the pleura as would be likely to make the one surface actually catch on the other; but then it will be observed that during the last five days of the patient's life there was no post-expiration sound heard.

With regard to the cause of this particular form of friction sound, there can be little doubt that the catching of the one surface on the other, and movement of the lung after the costal contraction of expiration has ceased, may both be factors in its production. The play of the one surface on the other, noiseless and frictionless in health, needs no remark; but it is also recognised that the lungs themselves, even at the end of expiration, are to some degree in a state of distension. "The elastic pulmonary tissue," says Foster, "is always to a certain extent on the stretch; it is always, so to speak, striving to pull asunder the pulmonary from the parietal pleura." Might we not rather say, at least of the lower lateral and posterior regions, "striving to pull down the pulmonary along the parietal pleura?" In the last case I imagine that it is quite likely that the movement of the lung surface after costal movement had ceased was the chief cause of the phenomenon; but my recollection of the other examples, of the sudden sharp sound like that occasioned by an elastic band being set free, conspicuously different from the rhythm of respiratory movement of any kind, completely convinces me that in these earlier cases the one surface was for the instant actually held by the other, and then suddenly let go. But I said I would do little more than record the fact. I would only add that of course in the case of the emphysematous chest the movement of air within the lung, especially if there be bronchitis, may often be conveyed to the ear after costal movement over the affected area has ceased, for obviously there might be almost no movement at all. But while that is also not without interest, the question is not now before us, and there was neither the emphysematous chest wall in any of the cases observed (though Dr. Steven found emphysema of one lung itself), nor did I ever confine my attention to the movement of any one part of the thorax, but observed it as a whole.

Glasgow.

REMARKS ON SOME FORMS OF ACUTE URINE FEVER IN SURGICAL PRACTICE.[1]

BY REGINALD HARRISON, F.R.C.S. ENG.,
SURGEON TO ST. PETER'S HOSPITAL, LONDON.

RESEARCH has made considerable progress since Civiale published his important treatise[2] on the subject, and we have now to discuss the pathology of urine fever from a bacteriological as well as a clinical aspect. It is, however, to the latter I shall chiefly address myself. In order that I may be as brief as possible, let me mention in a few words the type of cases I am referring to.

CASE 1.—A patient with a urethral stricture, but otherwise in good health and without any physical evidence of kidney disease, undergoes the comparatively slight operation of internal urethrotomy. Within a short time afterwards he is seized with a rigor, his temperature suddenly rises, and he perspires freely. This process, resembling in some respects a malarial fever, may or may not be repeated one or more times, and the patient makes a good and rapid recovery.

CASE 2.—To take another illustration, such as one amongst those recorded by Mr. Mitchell Banks.[3] A man about thirty years of age had a small bougie passed through a tight and long stricture commencing at two inches from the meatus, having on previous occasions, at short intervals, submitted to a similar proceeding. Half an hour afterwards he vomited, a rigor supervened, and the vomiting continued. Then the rigor was repeated, accompanied with a rapid pulse; a convulsive tremor followed, and death took place six hours and a half after the introduction of the bougie. Post-mortem examination records that beyond the presence of a long stricture and some slight congestion of the kidney all the organs of the body were healthy.

CASE 3.—I have published the particulars of the following case.[4] In 1886 I saw a healthy boy aged eleven years who had partially ruptured his membranous urethra by falling astride on his perineum. With a little trouble I passed a catheter and drew off over a pint of bloody urine. The catheter was retained. Forty-two hours after the injury he was seized with convulsions, which recurred at intervals, with much violence, attended with opisthotonos. He could not swallow though the jaws were not fixed, and he became comatose and died in eight hours after the convulsions set in, that is to say, fifty hours after the accident. An hour before death he had a temperature of 104° F. There was no post-mortem examination.

These cases, I submit, all belong to the same group, and though fatal instances are comparatively rare, most surgeons must have seen illustrations of them. That effects such as here shown are coincident with or consequent on bacteriological changes, primarily in the part injured and secondly by systemic infection, there can, I think, be no doubt. This aspect has been well studied by Dr. Noël Halle,[5] and the results of his investigations in M. Guyon's laboratory at the Necker Hospital are worthy of careful attention. It is to the clinical conditions which seem to favour or hinder the production of such bacteriological changes that I wish briefly to allude.

I was led up to making these observations by noticing the differences relative to the liability to a distinctive fever that existed between various kinds of lesions of the urinary apparatus. For instance, such an effect was rarely observed after cutting operations for the removal of stone from the bladder, or after perineal section for stricture, whilst in some degree it commonly occurred after internal urethrotomy. In a paper on this subject the late Mr. Teevan[6] referred to the frequency of rigors and fever after this operation as amounting to about two-thirds of his cases, a proportion much in excess of what is now observed where antiseptics are employed. Again, in accidental lesions of the deep urethra unattended with any breach of skin surface, as in those caused by falls on the perineum, it was frequently noted that rigors and fever supervened where their treatment was attempted by the retention of a catheter in the bladder by the side of which urine leakage took place, whereas in those instances where continuous urine drainage was provided by a free perineal incision such effects did not usually follow. Further, the occurrence of fever seemed in no way influenced by the degree of the lesion that was inflicted, some of the worst effects being noted after the passage of a bougie or catheter where the wound was extremely small, perhaps not amounting to more than an abrasion of the protective epithelium lining the urethra. Observations such as these appeared to indicate that certain distinctions in the mechanical construction of wounds were more potent contributory causes of what followed than mere textural limitations.

In view of such differences and the extreme frequency with which internal urethrotomy was then followed by varying degrees of fever, in some instances terminating

Digitized by Google

fatally with suppression of urine, and also having regard to the more permanent improvement of the stricture by the completeness of the rest afforded, I materially altered my plan of procedure. In a number of cases of advanced urethral stricture in the deep urethra, which did not yield to treatment by dilatation, I first made a section of the contraction from within the canal by Maisonneuve's urethrotome. This at once permitted the passage of a full-sized grooved staff, such as is employed in median lithotomy, along the urethra into the bladder. The patient being next placed in the lithotomy position, the median perineal boutonnière operation was then practised solely for the introduction of a gum-elastic drainage-tube of full calibre into the bladder. This was secured in position by tapes so as to cause the whole of the urine as excreted to escape through it. The drainage-tube was usually retained for about seven days and then withdrawn. As the perineal wound proceeded to heal, as it usually did in the course of a few days, a bougie was passed from time to time along the whole length of the urethra, so as to maintain the normal dimensions of the canal. Fuller particulars of this proceeding, together with a number of illustrative cases, were published some years ago,[7] and I have since continued to practise it in some kinds of advanced urethral stricture in preference to the ordinary form of perineal section, to which it only has a slight resemblance. The point, however, upon which I desire to lay stress in connexion with this proceeding is this—that the combination of internal urethrotomy with means for securing efficient urine drainage, independently of antiseptics, entirely prevented the rigors and fever such as were constantly observed when internal urethrotomy was alone practised—any exceptions to this rule being directly traceable to faulty urine drainage. In twenty-three consecutive cases where the double proceeding was practised, neither rigors nor fever were observed, the elevations of temperature, which were rarely noted, being such as are met with in the simplest forms of surgical practice. These observations corresponded with what was noted in connexion with the treatment of accidental lesions of the male urethra from falls and blows on the perineum, where the conditions were similar. From my experience of the rigors and feverish elevation of temperature occurring in connexion with lesions and operations involving the urinary apparatus, there appears to be only one form which is difficult of explanation by any septic view. This is the shivering which not unfrequently supervenes, when, after lithotomy and operations of a similar kind, urine is passed naturally along the whole length of the urethra for the first time. For some years past I have been practising perineal section of the enlarged prostate, when it caused such a degree of obstruction to micturition as not to be amenable either to catheterism or any other form of treatment. After division of the obstruction has been effected in this way a gum-elastic drainage-tube is introduced into the bladder and retained for some days, according to circumstances, so as to render the prostatic section permanent. Then the drainage-tube is removed and the perineal wound allowed to heal. I have now done a considerable number of these operations, and have frequently noted that when natural urination is for the first time resumed quite a sharp shivering attack almost immediately supervenes. This is usually followed by elevations of temperature which decline in a day or so. Two recent instances will be stated.

CASE 4.—On Feb. 9th, 1892, when performing lithotrity for a patient aged forty-nine, with a urate stone, a large triangular fragment became so firmly impacted in the urethra in front of the prostate that I completed the operation by a median cystotomy, through which I readily extracted all the débris. I put a large drainage-tube into the bladder. His temperature remained normal till the twelfth day, when he micturated naturally. This was immediately followed by a sharp rigor and an elevation of temperature to 100·4° F. No further rigors were noted, and recovery proceeded without interruption.

CASE 5.—On Feb. 27th, 1892, I divided the prostate of a patient aged fifty-three, who had been suffering from difficult urination, due to hypertrophy of the floor of the prostate for five years, having been entirely dependent on the use of the catheter for over one year. The latter became so irksome and painful to him that he determined to have the floor of the gland divided. This was done, and a drainage-tube introduced. No rigors or elevation of temperature followed. On the twentieth day the drainage-tube was removed, and he shortly afterwards micturated naturally for the first time for over a year. This was followed by a sensation of chilliness, headache, an elevation of temperature to 101·4° F., and a dryness of the skin with thirst. These symptoms declined, a free diaphoresis took place, and recovery was complete.

What is the significance of these manifestations? I believe their causation to be quite distinct from those previously referred to. In the first place, the sensation of chilliness commences on the conclusion of the first act of normal micturition; it does not usually recur; there is no incubative period. I am not aware of any evidence to show that these symptoms ever, either immediately or remotely, proved fatal or even serious, nor have any indications of a systemic or an infective nature, such as suppression of urine or suppuration, been observed in connexion with them. A rigor and the reaction following it is to be regarded as an expression on the part of the nervous system. It is by the circumstances attending the various manifestations of such a phenomenon that we are to judge how far the causes producing it are analogous. For the reasons I have stated it would appear that there is no correspondence in the two sets of conditions I have illustrated. Clinical observations relative to the whole subject seem to justify the conclusions (1) that the occurrence of a distinctive variety of acute fever following wounds of the urinary apparatus is largely determined by defective urine drainage; and (2) that the fever following these lesions is toxic and not neurotic.

In drawing the conclusion that urine fever is septic, I have not ventured to express an opinion as to the nature of the poison. Whether the poisonous effects are due to micro-organisms or to an alkaloid such as Bouchard[8] has described, has yet to be worked out. As bearing upon this point, let me quote a passage from an address by the late Dr. Austin Flint:[9] "The supreme objects of study in pathology at the present time are the discovery of micro-organisms and their natural history. But these agents, it is probable, are pathogenetic—not directly, but indirectly, by means of the toxical products of their activity. What are these products, and how do they give rise to the phenomena of disease? We may ask the same question of certain of the poisons introduced from without the body. How is it that fractional quantities of morphia, hyoscyamin, strychnia, aconitia, atropia, and other alkaloids produce their lethal effects? It conveys no adequate information to say that they act upon the nervous system. This is merely the statement of a fact, not an explanation. For the latter we must look to the organic chemistry of the future."

VACUOLATION OF NERVE-CELL NUCLEI IN THE CORTEX IN TWO CASES OF CEREBRAL CONCUSSION.

BY JOHN MACPHERSON, M.B., F.R.C.P. EDIN.,
MEDICAL SUPERINTENDENT, STIRLING DISTRICT ASYLUM.

WHATEVER views may be held as to the function of nerve nuclei by various authorities, there appears to be a consensus of opinion as to the importance of the nucleus of the cell in maintaining the vitality and function of the chain of nerve connexion in which it is a prominent factor. According to Meynert, "the nucleus exercises a nutritive influence over the albuminoid protoplasm of the cell; and the nutrition of axis cylinders and of their prolongations, some of which become nerve cylinders, is effected in a similar manner."[1] According to Bevan Lewis,[2] the nucleus exercises an inhibitory action upon the special function of the protoplasm of its cell. But there are two different opinions entertained as to the nature of the nerve cell itself, and consequently as to the inherent relation of the nucleus to the cell substance. The first opinion is what I shall call the *ganglionic theory*.

It is rather upheld by Max Schultze. This writer says: "Thus the cell constitutes a common point of union of numerous separate fibrils proceeding from widely different regions of the nervous system; and whilst one of these associated bundles becomes the axis cylinder of a fibre, and after becoming invested by a medullary sheath immediately runs peripherally, the others pass in unknown directions."[3] This view receives the support of many physiologists; recently Mercier[4] appears to take it for granted in an argument by which he endeavours to show from a teleological point of view the necessity for adopting this doctrine.

Such a view of nerve cells places them in the position of minute ganglia through which bundles of nerve fibrils pass in all directions, receiving in their passage nutritive and functional stimuli from the nucleus, which latter is said to be composed of embryonic protoplasm.[5] Certainly, the nuclear substance differs from the cell protoplasm in that it is not affected by dilute acids which destroy the cell substance. Further, it stains more intensely with some reagents (for example, hæmatoxylin) than does protoplasm; and, on the other hand, it remains unstained by reagents which colour protoplasm intensely—for example, chloride of gold.[6] The second view—that which regards the nerve cell as an independent unit from which arise the various cell processes—is championed by Meynert,[7] who shows that in young cells the nucleus is pyramidally shaped, like the cell itself, and that the angles and points of the nucleus are frequently produced into the processes of the cells—in short, that the axis cylinders are prolongations of the nucleus. This view is supported by Kühne's[8] researches, which show that both the nerve cells and the axis cylinders give the reaction for albumen, a kind of albumen which is insoluble in a 10 per cent. solution of chloride of sodium. Moreover, Mayer[9] has shown the continuation of the axis cylinder into the nucleolus. The same fact is supported by the observations of Beale.[10]

The whole question unfortunately still remains unsolved, for the lines of Schultze, which are so graphically represented in illustrations of large ganglionic cells running from process to process of the cell, and forming concentric circles round the nucleus, have been placed in an entirely new light. This striation, which Remak and Schultze[11] describe as fibrillar markings upon axis cylinders indicating bundles of nerve fibrils passing through the cell, has been shown by Rumpf to be folds of a keratoid sheath enveloping the cell, its processes, and the nerve fibres. There is, therefore, no direct observation upon the exact relation of the nucleus to the cell contents, and especially to nerve fibrils; but the strong presumption is that the axis cylinders and the cell processes originate in nerve nuclei. The reasons for this assumption are summarised by Meynert[12] as follows:—1. Because from the earliest period the nerve cells are independent units, and, according to Boll, the matrix protoplasm is the fused remnant of broken-up cells. 2. The cell processes originally start in the ganglion cell, and are mere prolongations of its protoplasm. 3. The axis cylinder develops out of special spindle cells in the medullary region, the protoplasm of which is continued into the grey substance of the cortex, and there splits up into very delicate fibrils which connect with the finest ramifications of the ganglionic processes. One fact is assured—viz., that the function of the cell nucleus in the cerebral cortex is of comparatively immense importance, for nowhere else in the body, except in the ovum, does the nucleus occupy so large a proportion of the cell space.[13]

The causes of nuclear vacuolation and the conditions under which it has been found to exist.—1. It has been held to be due to poisoning by phosphorus, antimony, or arsenic. Voit and Bauer produced vacuolation of the ganglionic cells of the spinal cord of dogs by poisoning the animals with phosphorus. Drs. Elkins and Middlemass[14] publish a case of phosphorus poisoning in which vacuolation of the nucleus, chiefly in the cells of the fourth layer, occurred conspicuously; and after a full description of the macroscopic and microscopic changes in the various organs of the body, they conclude "that the nervous system does not escape the action (fatty degeneration) which we know is capable of being produced by that poison in other organs. 2. It occurs in the course of various chronic degenerative changes in the brain, which are most commonly met with among the insane. Chief among those changes are the results of chronic alcoholic poisoning, where vacuolation of the nucleus may be met with throughout large areas of the sensory cortex. According to Bevan Lewis,[15] vacuolation of the nucleus is most commonly met with in the small cells of the second layer, and in that position constitutes the essential lesion of idiopathic epilepsy. He considers that in univacuolated cells the nucleus is the primary seat of the disease, and that the vacuolation is probably due to an intrinsic morbid factor in the cell itself.[16] Dr. James R. Whitwell,[17] in an article on the Nervous Element in Myxœdema, points out this condition to be one of the prominent pathological cerebral characteristics of that disease. In his report he states that the cells of the third and fourth layer were chiefly affected. In the cases which I describe below, and in which the changes were due, I think, entirely to direct cerebral violence, the vacuolation of the nuclei exists chiefly in the third and fourth layers of the motor and frontal cortex, and are in one of the cases only faintly apparent in the layers of the occipital and specially sensory cortex.

The manner in which head injuries act upon the brain cell is undoubtedly by affecting the blood and lymph circulation in the perivascular channels and the pericellular sacs. The reasons for holding this view are:—1. The extreme rapidity of the occurrence of the pathological change in question—after concussion, for instance. In Dr. Miles'[18] experiments the cellular degeneration was produced within fifty hours, and in one of the following cases within forty-eight hours. 2. The larger cells suffer primarily and chiefly. It is quite conceivable, and the theory is supported upon the authority of Ross,[19] and may, I think, be conceded that the larger cells suffer earlier than the smaller ones because of their greater bulk, and that their nuclei are principally affected on account of their distance from the circulating lymph and the consequent nutritive disadvantage of position. Where there is an interference with the free circulation of pericellular lymph, it is quite apparent that its action on the cell should be poisonous and destructive. Normal cerebral lymph is an alkaline fluid. After death,[20] or in pathological conditions,[21] it becomes acid. The chemical nutritive action of an alkaline secretion one would be inclined to suppose on *a priori* grounds to be entirely different from that of an acid one. That a vascular change accompanies chronic cell degeneration in insanity—such as alcoholism, general paralysis, and dementia—is undoubted, but the disputed point has all along been whether the cell degeneration or the vascular change was primary. That question, however, is not suitable for discussion here, but it may on all hands be conceded that a vicious circle of cause and effect is established.

In phosphorus poisoning the constituent elements of the vascular system seem to be simultaneously affected with the epithelial and other cells, including nerve cells,[22] the change which takes place being a nutritive one, and consisting in the rapid disintegration of albumen and its conversion into fat.[23] The cell change in concussion is undoubtedly of primary vascular origin, although, according to Miles,[24] there are actual gross protoplasmic disturbances in the cell, such as displacement of the nucleus and commencing pigmentation of the cell protoplasm. Duret[25] describes the vascular changes that occur after severe concussion. He states that there is first of all extreme vaso-motor contraction, due to over-stimula-

tion of the vaso-constrictor centre in the floor of the fourth ventricle and the restiform bodies, by the excessive and sudden accumulation of cerebro-spinal fluid in that cavity, and that after a longer or shorter interval there is vaso-motor paralysis of the cortical arteries with consequent dilatation of their walls, and a tendency to congestion and stasis.

Again, Meynert[26] holds that the cortex itself is a vaso-motor centre which, when active, inhibits the lower (sub-cortical) centre, thus causing dilatation of its own arterial system. It thus becomes a workable theory that in concussion there is first arterial contraction due to mechanical stimulation of the vaso-motor centre in the medulla, and, secondly, arterial dilatation due to a morbid activity of cortical cells after the shock-producing inhibition of the same vaso-motor centre. The bearing of these observations upon the question of cell nutrition and cell degeneration is not affected by the fact that in the majority of cases the condition of vaso-motor paralysis is a temporary one. It may be sufficiently prolonged to produce death by impairing the nutrition of the thermotaxic cells in the motor cortex,[27] or it may occur some time after the injury, or, again, it may be permanent,[28] producing delirium, insanity, coma, or death.

CASE 1.—Male, aged fifty-six, a monomaniac, with delusions of grandeur, who had been insane for at least six years, fell backwards upon a stone floor. The occipital part of his head came into violent collision with the floor, producing fracture of the base of the skull, as was manifest shortly afterwards from the bleeding at the ears and nose. He became slowly comatose, and in seven or eight hours after the receipt of the injury he could with difficulty be awakened. This condition deepened, and he gradually sank, the vital functions becoming perceptibly weaker; he died forty-seven hours and three-quarters after the injury. On post-mortem examination a basal fracture of the skull was found passing from behind the foramen magnum, and ending in the petrous portion of the temporal bone of the right side. The left lobe of the cerebellum and the tip of the right frontal lobe were lacerated as the result in the latter case of *contre-coup*. The laceration was so pulpy as to bear out Duret's theory of the movements of the cerebro-spinal fluid during concussion and his *cone soulèvement*.[29] The amount of blood effused inside the cranium, considering the extensive nature of the injuries, was extremely small, being not, in my opinion, sufficient to produce the so-called pressure symptoms. Compression as a theory to account for death after head injuries has hitherto been too universally accepted, and it is necessary carefully to discriminate between cases of actual compression due to effused blood and cases where the amount of blood effused is insufficient to account for the symptoms. This patient died in the reaction stage, or the stage of vaso-motor paresis, or what Mr. Hutchinson calls the sleepy stage of concussion.

CASE 2.—A young man aged seventeen was admitted to this asylum in a state of delirious mania. Two or three days previous to admission he had been struck on the back of the head with a stone by another lad. From the symptoms described by his friends he had evidently suffered from concussion at the time. That evening and during the day following the accident he complained of intolerable *frontal* headache, and on the succeeding day thereafter he became maniacal. When admitted his temperature was 99° F., it gradually rose, until on the third day after admission it stood morning and evening at 101·4°. From that day until the day of his death there was a steady fall of the temperature. On the latter day the thermometer registered 96·8° F. His extremities became cold and the radial pulse imperceptible upon the fourth day after admission. These symptoms of failing vitality resisted the most stimulating treatment. Post-mortem examination revealed a fissure fracture a little to the left of the occipital protuberance. There was no depression, no meningitis, and no effusion; nor was there laceration of the brain, or hæmorrhage into any part of the cortex or ganglia of the brain. This, then, is an uncomplicated case of cerebral concussion, which corresponds to Duret's description of fatal concussion, where, as he says, the vascular paralysis passes into inflammatory reaction, when the nervous symptoms persist until death closes the scene.[30] At another part of his work he says: "Sometimes after the loss of consciousness there is recovery, which lasts for one or for many hours; there may even be complete restoration. Then the animal becomes gradually comatose, his faculties become overclouded, and he falls into a deep sleep."[31] We see, then, from the results of Duret's experiments, and from his observations, that vascular paralysis, passing on to a state equivalent to inflammatory congestion, may supervene at a considerable time after concussion.

Microscopic changes in the brain in both cases.—In both cases in the cells of the third and fourth layer of the motor and frontal regions there were universally found distinct, refractile particles in the centre of the nucleus. These were without question vacuoles. In some nuclei I counted as many as three of these bright spots, but in the great majority of cells only one vacuole occupies the centre of a nucleus. In Case 2 the affected cell nuclei are large and swollen, irregular in outline and shape, and stain (Bevan Lewis's method) very darkly with aniline blue-black. The cell processes for some reason do not stain well, giving an appearance as if they were broken off or stunted. In Case 1 the nuclei do not seem to be enlarged, but there is extensive granular and commencing pigmentary degeneration of the cell protoplasm. I do not attach any importance to these latter changes, for although they may possibly bear some relation to the injury, yet they are so commonly met with in the brains of persons labouring under chronic insanity that they must be discounted in the present case. With regard to the localisation of the lesions in both cases, I have already referred to the greater immunity of the smaller cells of the cortex from the effects of rapid nutritive changes. It must, however, be admitted that there are cells in the regions of the brain posterior to the ascending parietal convolution larger than many of the affected cells in front of Rolando's fissure. How, then, can the immunity of such cells in the posterior cortical regions be accounted for? To quote Duret again:[32] "Each variety of shock most frequently produces its special lesions at the place of *contre-coup* ["suivant le lieu de sa repercussion."]..... When the shock is applied to the occiput the effects are seen in the frontal lobes and at the posterior part of the hemispheres. This is undoubtedly the case, and we are justified in attributing the cellular change to the effects of *contre-coup*, as in both cases the force was applied to the occipital region of the head. Meynert[33] points out that functional hyperæmia of the cortex differs from that of any other organ, such as the liver, in that it is capable of being localised to functionating regions; all other regions not associated at the time remain non-hyperæmic. If, then, after dynamic or inherent molecular disturbance, such as must be caused by direct force and the apnœic state caused by vascular spasm, there is a morbid exaltation of cell energy, there will be an accompanying hyperæmia limited to, or chiefly limited to, the region of nervous hyper-excitation, and this condition may persist.

My conclusions, then, are: (1) That a nuclear nerve cell lesion in the cortex is a condition of great importance, and indicates an interference with the vitality and function of the cell; (2) that it is capable of being produced by vascular changes which affect the nutrition of the cell; (3) that when the lesion is situated chiefly in the motor cortex it tends to interfere with the vital functions by the implication of the thermotaxic cells; (4) that important vaso-motor changes occur after concussion which are the result either of exhaustion of the subcortical vaso-motor centres from over-pressure or of their inhibition by hyperaction of the cortical cells implicated.

ACUTE INTESTINAL OBSTRUCTION DUE TO A LARGE GALL-STONE; OPERATION.

BY A. A. BROCKATT, M.D. BRUX., L.R.C.P. LOND., &c.

J. B——, aged forty-three, had been a village schoolmaster for the last seventeen years and led a sedentary life. He had lived well for his position, indulged in a moderate amount of stimulants, and eaten freely. Up to Feb. 22nd, 1891, he had had no illness of any importance. On that date Dr. Murphy of West Malvern was called in for an acute attack of pain in the epigastric region, which subsided in twenty-four hours. The pain does not appear to have had the character of biliary colic. There was no jaundice or vomiting, and for some time previously the patient had been taking huge quantities of cod-liver oil, under the impression that his chest was weak. On Dec. 20th, 1891, Dr. Murphy was called in again for a supposed bilious attack. The patient had been vomiting more or less continually for three days, and the first thing that struck Dr. Murphy was the reduction in the size of the patient that had taken place during the six months that had elapsed since he had seen him; previously he had been a man of 14 stone weight, now he was under 12 stone. His face was pale and pinched, with an anxious expression. The vomiting had come on suddenly three days before, and was copious and bile-stained. There was no pain, and for two days the bowels had been confined, notwithstanding he had been taking purgatives. He complained of great thirst, there was entire loss of appetite, and the temperature was normal. There was nothing abnormal to be detected in the abdomen by Dr. Murphy except a distinct feeling of resistance to the right of the umbilicus. He prescribed for him five grains of calomel, to be followed by an enema, and a bismuth mixture. On the 22nd there had been a slight action of the bowels, the vomiting was less frequent, and the patient expressed himself as feeling better. Dr. Murphy administered a copious enema, which was followed by three large stools. The first showed traces of the action of the calomel, and the following were black from the bismuth. There was a great deal of flatus. On the 23rd the patient partook of some chicken, and the vomiting became much more frequent, was very copious, and contained large quantities of bile. He continued in much the same condition until early on Dec. 25th, when the vomit became very offensive and was more or less continuous.

I was called in to see him in the evening, and found the abdomen much distended. He was extremely restless; his pulse was 120 and the tongue dry and brown. He did not complain of pain, which symptom, indeed, he said had been entirely absent during the whole of his illness. It was decided to perform abdominal section early the next morning. On Dec. 26th Dr. Pike administered chloroform to the patient, whose condition was unaltered from the previous night. When under the anæsthetic a hard mass, freely movable, was detected in the right iliac region. I opened the abdomen in the middle line below the umbilicus and found the lump to be a hard mass, which completely blocked the lumen of the small intestine. The intestine above was much distended and around the mass was so tightly stretched that it was completely immovable. The coil of intestine was then brought outside the wound, and, Dr. Murphy holding it firmly above and below the obstruction, I incised it in its long axis opposite the attachment of the mesentery. The obstruction proved to be a large gall-stone, and was easily extracted. The intestine near was then thoroughly washed out and the wound united with Lembert's sutures. Two vessels in the mucous coat, which bled rather freely, were previously tied.

On account of the critical condition of the patient a further examination of the abdomen was out of the question, so the abdominal wound was closed as quickly as possible, and a drainage-tube inserted into the peritoneal cavity. He was ordered nutrient enemata and a grain of opium every six hours. On Dec. 27th the patient had recovered completely from the shock of the operation, and expressed himself as feeling quite well—indeed, he had to be very closely watched to prevent him getting out of bed. His temperature was normal, he had no pain or tenderness, and his pulse was 96. There had been no return of vomiting. The next day he still expressed himself as feeling better. There were no abdominal symptoms, and the wound when dressed was quite healthy. On Dec. 29th, as he felt very weak, a small quantity of milk was ordered to be given every hour in addition to the nutrient enemata. There were still no abdominal symptoms; the drainage-tube was removed. On the following day he was much weaker, so essence of beef and milk were administered in small quantities every quarter of an hour, but he gradually became more exhausted, and died on the afternoon of the 31st, the sixth day after the operation.

Only a partial examination was allowed by the friends. The abdominal wound was healed, except at the part where the drainage-tube had been inserted. There was slight peritonitis of some of the superficial coils of intestine on the right side in the neighbourhood of the intestinal wound. This was firmly united, and was situated high up in the jejunum. On tracing the small intestine upward it was found to be firmly matted together by old adhesions, and the gall-bladder was firmly incorporated with the mass, and could not be separated. The liver was apparently healthy. The gall-stone, an unusually large one, was pear-shaped, and measured 2 in. in length, 1⅞ in its greatest transverse diameter, and 5½ in. in its greatest circumference.

Great Malvern.

THE SCIENTIFIC PRINCIPLES OF INHALATION.

BY ROBERT LEE, M.D. CANTAB., F.R.C.P. LOND.

IN the report of the Medical Officer of the Privy Council, 1875, there is a paper by the late Dr. Baxter on the action of certain disinfectants on vaccine lymph. The chief object of the experiments was to determine whether the vapours of chlorine, sulphur dioxide, and carbolic acid acted on lymph in the same way as their solutions. There was a difficulty at the outset which Dr. Baxter recognised. "It was well-nigh impossible," he said, "to obtain an atmosphere containing a given percentage of the vapour"; and he imagined that if he fixed ivory points charged with vaccine lymph in a bottle containing strong carbolic acid, so that they were about half an inch above the fluid, the vapour would act upon them. Practically it had no effect; for the points answered well when used for vaccinating with. Now, to conclude that the vapour had no effect when he had proved before that the solution had was an error which arose from the fact that carbolic acid does not give off vapour to any active extent at a temperature of from 60° to 65° F. By applying this example to the subject of inhalation it must be evident that it is necessary before we can judge of the value of any vapour we should know something of its strength, just as if it were a solid or a liquid. In the case of carbolic acid we can do this; because if we mix the acid with water in any proportion and then boil the mixture, the steam and the acid are given off together, and in the same proportion as they existed in the water. Thus we can obtain vapour containing any percentage of carbolic acid. But with the turpentines and essential oils which float on the surface of water it does not seem that mixing with water, or rather floating them on water, makes any difference to their volatilisation. If the water be boiled, the bubbles of air rising through the layer of oil have apparently the same effect as a stream of hot air would have, and the amount of oil which volatilises will depend on its temperature of volatilisation.

In the British Pharmacopœia for 1885 six vapours or inhalations were introduced, but no consideration had been given to the important questions which should have been determined before they could be prescribed with any accuracy or practical benefit. In the case of the vapour of hydrocyanic acid, it is simply the question of temperature on which evaporation of the acid depends. With the vapor chlori no vapour ought to be given off when pure chlorinated lime is moistened with cold water, or, as Dr. Baxter remarked; "it is sufficiently obvious that the quantity of chlorine given off into a room from a basin filled with chloride of lime.....would be utterly inadequate to destroy vaccine virus." In the case of the vapor coninæ it may be observed that between six and seven minims of succus conii on a sponge, exposed to the vapour of hot water, must yield a vapour of the feeblest character, for the dose of the juice is from half a drachm to one drachm. At least one would like to

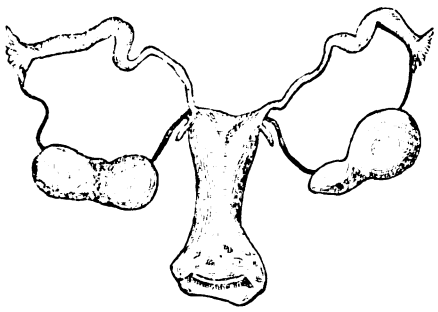
THE SCIENTIFIC PRINCIPLES OF INHALATION.



By ROBERT LEE, M.D. CANTAB., F.R.C.P. LOND.

In the report of the Medical Officer of the Privy Council for 1865, there is a paper by the late Dr. Baxter on the action of certain disinfectants on vaccine lymph. The chief object of the experiments was to determine whether the vapour of carbolic acid, sulphur dioxide, and carbolic acid acted on vaccine lymph in the same way as their solutions. There was a difficulty at the outset which Dr. Baxter recognised. "It was," he said, "impossible, be said, "to obtain an atmosphere of vapour of a given percentage of the vapour"; and he endeavoured to meet it by fixing ivory points charged with vaccine lymph in a bottle containing strong carbolic acid, so that they were suspended about half an inch above the fluid, the vapour would act upon them. Practically it had no effect; for the points when used for vaccinating with. Now the answer is well when used for vaccinating with. Now the answer is that the vapour had no effect when he had proved to him that the solution had was an error which arose from the fact that carbolic acid does not give off vapour in accordance with that carbolic acid does not give off vapour in accordance with Raoult's law at a temperature of from 60° to 65° F. But this example to the subject of inhalation it must be remembered that it is necessary before we can judge of the value of a drug or we should know something of its strength—whether it were a solid or a liquid. In the case of carbolic acid we can do this; because if we mix the acid with water in any proportion and then boil the mixture, the whole of the acid are given off together, and in the same proportion as they existed in the water. Thus we obtain vapour containing any percentage of carbolic acid we like. But with the turpentines and essential oils which float on the surface of water it does not seem that anything of the kind occurs, or rather floating them on water, gives off, or, rather floating them on water, gives off, in accordance to their volatilisation. If the water be made to boil and the bubbles of air rising through the layer of oil of turpentine apparently the same effect as a stream of hot air would, and the amount of oil which volatilises will depend on the temperature of volatilisation.

In the British Pharmacopœia for 1885 six vapour inhalations were introduced, but no consideration of the important questions which should have been determined before they could be prescribed with any certainty or practical benefit. In the case of the vapour of carbolic acid, it is simply the question of temperature of evaporation of the acid depends. With the vapour of turpentine ought to be given of when pure oil of turpentine is moistened with cold water, or, as Dr. Baxter remarked, "it is sufficiently obvious that the capacity of the room from a basin filled with the oil of turpentine given off into a room from a basin filled with the oil of turpentine would be utterly inadequate to destroy any disease germs which would be utterly inadequate to destroy any disease germs which might be in the case of the vapour coming it may be diffused in a room of 1000 cubic feet capacity, seven minims of eucalyptus oil would be required to produce a vapour of hot water, must yield a vapour of between and seven minims of eucalyptus oil would be required to produce a vapour of hot water, must yield a vapour of the same strength as that

tion of the pulmonary orifice was also found, together with the ordinary signs of mitral disease.

CASE 2.—The accompanying sketch was taken from a specimen removed from an infant brought in dead to the

hospital, the death being due to bronchitis. The right ovary was represented by two cysts, which were perfectly translucent, and separated from one another by a distinct partition, no trace of normal ovarian tissue being present. The left was healthy for its proximal half, the distal half being occupied by a rounded and translucent cyst.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

TUBERCULAR DISEASE OF RIGHT KIDNEY; NEPHROTOMY; REMOVAL OF RIGHT KIDNEY; ANURIA; URÆMIC CONVULSIONS; DEATH; ATROPHY OF LEFT KIDNEY.

(Under the care of Mr. PAUL SWAIN.)

IT is only right as a guide and warning to others that unsuccessful cases should be published. This was a case in which it was thought possible that a renal calculus might be present, as the renal symptoms were entirely right sided. It was therefore thought advisable to explore the right kidney. This exploration was unfortunately followed by rapid enlargement of the kidney and aggravation of all the symptoms. In addition, there was such rapid emaciation and loss of strength that it was evident, unless something was done, the man would die of septic absorption from his suppurating kidney. The rapid enlargement was attributed to inflammation and formation of pus in the kidney. That the enlargement noticed at the first operation was due to compensatory hypertrophy did not occur to anyone, as there was nothing to cause suspicion that the left kidney was destroyed by disease. In fact, it was not until the anuria had lasted twenty-four hours that it occurred to the operator that the working kidney had been removed. The association of chronic cystitis with dilatation of the ureters, atrophy of the left kidney, and hypertrophy of the right is rather difficult of explanation. The chief difficulty is to decide the sequence of events. Perhaps the following explanation may suffice. First there was cystitis, which caused thickening of the bladder and frequency of micturition, which two elements caused the dilatation of the ureters. Following this came suppuration in the left kidney, leading to atrophy of its substance and compensatory hypertrophy of the right kidney, in which tubercular disease ultimately supervened. In this case, as so often happens where the working kidney is removed, the patient remained conscious to the end. The convulsions which occurred were very slight, the most distressing symptoms being the incessant hiccough and vomiting. For the notes of the case we are indebted to Mr. W. Gifford Nash, late house surgeon.

W. S——, aged thirty-five, a police constable, was admitted on June 9th, 1891, supposed to be suffering from renal calculus. His symptoms were aching pain in the right loin radiating to the groin and testis, worse after walking about, and frequency of passing urine by day and night, followed by pain along the urethra. He stated that for two years and a half he had micturated about every twenty or thirty minutes by day and night. He had had pains in both loins, but chiefly the right. Two years ago he had a severe attack of pain on the right side and passed blood, and since then he has done so four or five times. Large clots have been passed, and much slimy sediment. There was never any definite attack of renal colic. He had gone down in weight from 180 lb. to 150 lb., but was able to follow his work as a constable until a week before admission. He had served four years in India, and passed through the Egyptian War. There was no known family history of tubercular disease.

On admission the patient was a large-framed man, fairly well nourished, but rather anæmic. The kidneys could not be felt, but there was decided tenderness in the position of the right kidney. The testes were normal. The bladder was sounded, and was decidedly tender. The urine contained one-twelfth of albumen due to the presence of pus. The heart and lungs were healthy. The evening temperature was about 101° F. each night.

On June 12th, under chloroform, the right kidney was explored from the loin. It appeared enlarged, and its surface mottled. It was punctured in four or five places, and its pelvis and calyces explored through an incision in the cortex. Nothing was found. A drainage-tube was inserted down to the kidney, and the wound in the loin sutured. After the operation the amount of urine passed was much increased, the daily average being seventy-three ounces, and on June 25th and 26th it was 122 and 101 ounces respectively. The quantity of pus varied from one-twelfth to one-thirtieth. On June 26th there was noticed a great increase in the size of the right kidney, and on the 29th urine began to flow from the lumbar wound, which was not healing well. The temperature was getting higher, and the man rapidly lost flesh and strength, besides suffering more pain in the loin. It was thought that the kidney was becoming disorganised, and had better be removed. There was nothing to lead anyone to think that the left kidney was absent. On July 3rd the right kidney was removed, and with it a large mass of condensed and hard perinephritic fat. The kidney removed weighed thirteen ounces, and the fatty capsule six ounces. The nephrotomy wound entering the pelvis of the kidney was not healed. The cortex of the kidney contained numerous small suppurating foci, and at one spot an abscess cavity the size of a filbert, which had burst into a calyx, the lining of which was ragged and ulcerated. The lining of the pelvis was rough and thickened. The kidney tissue generally was pale and tough, but at several spots were infarctions of recent date.

July 4th.—In twenty-four hours following the operation four ounces and a half of fluid were passed, consisting almost entirely of blood and pus. Temperature subnormal; pulse 70; respiration 22.

5th.—During the last twenty-four hours the patient has been frequently sick, and has passed five ounces of bloody fluid. He has no headache or pain, and is quite wakeful. At 3 P.M., forty-nine hours after the operation, slight general convulsions occurred.

6th.—At 3 and 4 A.M. again was convulsed. He has passed seven ounces and a half of fluid, which is clearer and contains one-third of albumen and one-fifth of pus. Pulse 84. Tongue red and dry. Sickness continues.

7th.—He has passed three ounces and three-quarters of urine. There are constant hiccough and vomiting. He remained conscious until death at 7.30 A.M. In eighty-nine hours and a half after removal of his working kidney he passed twenty ounces and three-quarters of blood-stained urine.

Post-mortem examination.—The bladder, ureters, and left kidney were removed *en masse*. The left kidney was about the size of a testis weighing half an ounce. Its upper half consisted of a cavity filled with white pultaceous material, and the lower half appeared fairly healthy. The left ureter was dilated to the size of an index finger throughout its whole length. The right ureter was rather smaller. The vesical orifices of both ureters were pervious. The bladder was contracted, very much thickened, and rugose. There was no urethral stricture.

HOSPITAL SATURDAY AT BIRMINGHAM.—The total subscriptions this year amount, so far, to £10,812, as against £9862 up to the same date in 1891. Exceptional interest is attached to the collection this year, having regard to the new convalescent establishment at Tyn-y-Coed in connexion with the Hospital Saturday Fund. It was estimated that £12,000 would be needed, but it will be seen by the figures given that a considerable sum will be required in order to reach the desired amount.

CLINICAL SOCIETY OF LONDON.

Enterectomy.—Spontaneous Cure of Aneurysms of Femoral Artery.—Non-tubercular Hæmoptysis in association with Renal Cirrhosis.—Tubercular Disease of Breast and Axillary Glands.

AN ordinary meeting of this Society was held on May 13th, Dr. Charlton Bastian, Vice-President, in the chair.

Mr. F. PAUL gave the particulars of a case of Enterectomy. In this instance he had put into practice an operation devised for uniting intestine, and published by him in THE LANCET for May, 1891. The patient was a woman aged thirty-seven, in whom a strangulated hernia had gone unrelieved for at least six days. The bowel was sloughing, and had to be excised. It was reunited in the following manner:—A bone tube armed with a traction thread was sewn into the upper end. The traction thread was passed through the wall of the lower end about three inches down, and the two cut ends were lightly attached to each other. Then while an assistant held the traction thread, the operator invaginated the bowel over the tube so as to completely cover the cut. It was retained in this position with four Lembert sutures, and the traction thread was drawn tight and cut off short. The patient was fed freely with fluid nourishment from the first. Solid food was commenced in the form of bread and milk on the sixth day, and meat on the fourteenth day. On the eighth day the bowels were well moved by glycerine enema, and subsequently at intervals of a few days. The pulse and temperature remained practically normal, and there were no symptoms worth recording. In three weeks she was allowed up, and at the end of the month left the hospital quite convalescent. At the present time she was quite well, and the bowels in every way natural.—Mr. HOWARD MARSH observed that the procedure was a remarkably simple one, and might be taken up by any intelligent surgeon at once and easily carried out.—Mr. BOWREMAN JESSETT remarked that it was often a very difficult proceeding to effect invagination in dogs. He thought that puncture of the lower segment of the bowel might, at any rate in certain cases, prove a source of danger. In his opinion all invagination operations were difficult and even impossible when there was much distension of the bowel above the stricture. He had himself employed the operation of lateral approximation, and invariably with a good result. Referring to Mr. Robinson's operation, he observed that the use of a rubber tube in the distal portion of the gut was not unlikely to lead to subsequent complications; as compared with the bone tubes suggested by the author, the rubber had the disadvantage of not being capable of absorption. While the author's procedure certainly constituted a step in advance in intestinal surgery, he did not think they could flatter themselves that they had attained perfection. Passing on to consider the question of which was the best suture to employ, he said he had observed that in certain cases Lembert's suture showed a tendency to tear—a contingency which could be effectually provided against by employing a "quilled" suture, which gave a firm grip on the tissues. The stomach should always be washed out as a preliminary proceeding.—Mr. PAUL, in reply, agreed that the experimental operation presented some difficulty in dogs, on account of the greater thickness of the muscular coat of the intestines of that animal; but the muscular resistance could be overcome by sustained pressure. He could not believe that the minute puncture of an ordinary sewing needle with its thread could ever be productive of harm; in any event, he had never seen any harm result from it. In reference to Mr. Jessett's suggestion as to the advantages of lateral approximation, he observed that their experience of this procedure in Liverpool in gastro-enterostomy had been unfavourable in that the aperture showed an insurmountable tendency to subsequent closure. He was not disposed to deny that Robinson's operation might ultimately prove to be the easiest. He himself had made some attempts in the same direction, but had been deterred from further attempts on finding that the manipulation of the intestinal walls led to gangrene.

Mr. HOWARD MARSH related a case of Spontaneous Cure of an Aneurysm of the Femoral Artery, apparently by inflammatory action. The patient was a street paviour, aged forty-three, and was admitted into St. Bartholomew's Hospital, under the care of Sir William Savory, on March 20th, 1891, with a well-marked aneurysm of the femoral artery, of the size of a small orange, in Hunter's canal, attended with œdema of the leg and considerable pain. The skin over the tumour was somewhat suffused and hot, the cutaneous veins were distended, and the surface was tender. The patient's temperature was 100·2°. On the following day, while the patient was lying in bed with the limb slightly raised and at rest, pulsation diminished, and in eight or ten hours entirely ceased, and the tumour, except at its central part, became firm and hard. From this time the swelling gradually diminished in size, and the patient was discharged on June 12th. On Sept. 1st he was readmitted with a second and smaller aneurysm of the femoral, immediately above the former one—i.e., in the upper part of Hunter's canal. He was placed in bed, and next day the aneurysm also was found free from pulsation and apparently solid. The tumour slowly disappeared.

Dr. FRANCIS HAWKINS gave the particulars of a case of Non-tubercular Hæmoptysis of Fourteen Months' Duration occurring in association with Cirrhosis of the Kidneys. The patient was a man aged forty-two, a carriage painter, who complained of "spitting blood" at intervals for twelve months. The patient had been treated for tuberculosis before coming under observation. Hæmoptysis was sudden in its onset; the blood was frothy and light in colour, and about one pint in quantity. The patient had never been ill previously. He was a well-built man, with pale skin and sallow tinge. The heart was much hypertrophied, and there was general arterio-sclerosis. At the post-mortem examination both kidneys were very small, capsule adherent, and the kidney contained small cysts. The left lung at its base presented the appearance of carnified lung; at the apex it was emphysematous and œdematous. The right lung was emphysematous, congested, and œdematous. Attention was drawn to the fact that hæmoptysis might occur as a symptom in renal disease, and that a hypertrophied heart might produce physical signs in the left lung which might be mistaken as evidence of tuberculosis.—Dr. HADDEN inquired whether at the post-mortem examination any traces of previous hæmorrhages had been found in the lungs, and whether any sanguineous extravasations had been found in any other organs of the body. Hæmorrhagic extravasation confined to the lungs was, he thought, rare in chronic renal disease.—Dr. BENHAM did not think it had been clearly shown that the hæmorrhage actually came from the lungs. The author, indeed, had mentioned that the blood came away on several occasions without any effort of cough. He mentioned that in one case of supposed hæmoptysis in his own practice he had found on examining the mouth that on the site of a tooth stump there was a small pulsating vessel which was evidently the source of the hæmorrhage, though this had lasted for several weeks. He asked why the author had not used turpentine instead of ergot; the former he regarded as the more valuable hæmostatic in such cases.—Dr. BASTIAN suggested that the hæmorrhage might possibly have been due to rupture of varicose veins in the respiratory tract—a condition of things which would be very likely to escape observation at the necropsy. This condition was probably the source of unexplained hæmorrhages from the stomach in cases in which the symptoms did not authorise the supposition of ulcer.—Dr. CHAPMAN mentioned a case in which the passage of a small shot into the bronchi had determined paroxysmal hæmoptysis, which only ceased, and the cause of which was only ascertained, on the shot being expectorated.—Dr. LONGHURST asked whether there was any history of syphilis. He thought that the hæmoptysis might have been due to a gumma of the lung. This was suggested by the excellent effects obtained by the administration of iodide of potassium.—Dr. HAWKINS, in reply, said that every possible source of hæmorrhage had been eliminated by a careful search. There was no history or obvious indication of syphilis.

Mr. ARBUTHNOT LANE read a paper on Two Cases of Tubercular Disease of the Breast and Axillary Glands. He alluded to the frequency of chronic mammary abscess in women, giving strong tubercular histories or exhibiting this disease in other organs, and considered that though these were usually unassociated with tubercular disease of the

Digitized by Google

axillary glands, they were nevertheless tubercular. The first case was that of an unmarried woman aged thirty-eight, who had had to her knowledge a tumour in the breast for eighteen months, which had recently been associated with a swelling in the axilla. She had no evidence of tubercle elsewhere, nor was there any history of tubercle in her family. She recovered after the breast and a large number of caseous glands had been removed, and she had no recurrence of the growth, locally or elsewhere. The second case was that of a married woman aged thirty-four, who gave a strong tubercular family history. During lactation an abscess developed in her breast, burst, and discharged at intervals. An abscess developed later in the axilla. She was seen by Mr. Lane four years after the development of the abscess, when the breast was found to be riddled with sinuses, and the axilla filled up with caseous and suppurating glands. These were removed with great difficulty. Except for some induration in the apex of the axilla, the patient recovered completely. She had no evidence of tubercle elsewhere.

PATHOLOGICAL SOCIETY OF LONDON.

Mammary Tumour.—Indigo in Urine.—Lesions of Pyramidal Cells in the Cerebral Cortex in Chorea.—Sarcoma of Thigh.—Malignant Orbital Growth.—Hereditary Sarcoma of Eyeball.—Congenital Heart Disease.—Congenital Cyst beneath Tongue.

AN ordinary meeting of this Society was held on May 17th, the President, Sir George Humphry, in the chair.

Mr. C. B. LOCKWOOD showed a tumour of the breast which had the characters of a maligunt duct papilloma, or, as it is more commonly called, duct cancer. It had been removed by Mr. Willett from an unmarried woman aged thirty-nine, and the history was typical of that affection. The disease began, eighteen months before removal, with pain, which became persistent. The left breast then seemed harder than the right, and there was a discharge of blood from the nipple—small at first, then gradually increased until a teaspoonful was lost in the twenty-four hours. Physical examination showed that the left breast was larger than the right, and hard and nodular. Above the outer side of the areola there was a harder mass, and when this was pressed blood exuded from the nipple. There was also a slightly enlarged gland low down in the axilla. The mammary gland and two of the axillary glands were removed by operation, and the patient made a safe and rapid recovery. When examined with the naked eye the diseased structures had not the usual appearance of carcinoma. The masses in the substance of the mamma seemed more like inflammatory indurations. Throughout the gland, however, a number of small apertures could be seen, and were judged to be the mouths of enlarged and patulous ducts. This was borne out by the histological examination, which not only showed that the lumens of the ducts were enlarged, but that epithelial papillæ projected into them. Such appearances as these would not have constituted a cancer; but, in addition, the epithelial lining of the ducts had in numerous places proliferated and invaded the connective tissue of the breast, which was increased in quantity. The lymphatic glands which had been removed from the axilla seemed to contain no trace of cancer. In conclusion, Mr. Lockwood said he ventured to show the specimen, as it illustrated an unusually early stage of an interesting disease.—Mr. RAYMOND JOHNSON doubted if the specimen was of a carcinomatous nature, and considered that it was more probably proliferated epithelium into the cysts of a degenerated mamma. Three pathological processes could produce the conditions seen in the sections: (1) simple intra-cystic papilloma; (2) cystic carcinoma; and (3) duct papilloma. He then referred to a card specimen shown to the meeting by Mr. Bland Sutton. The appearances seen in Mr. Lockwood's sections might possibly indicate a condition of mamma antecedent to rather than actual carcinoma.—Professor HAMILTON of Aberdeen asked if this case was not really an instance of combination of papilloma with cancer. He had recently met with such a case, in which in one part of the breast there was typical scirrhous cancer, and in another part cysts containing papillary growths. Such a combination of growths was most unusual.—Mr. BLAND SUTTON said that his specimen showed a mass of papillomatous growth projecting into a cyst lined with epithelium. These projecting processes were essentially of warty character. There was no interstitial growth in the stroma of the breast.—Mr. LOCKWOOD, in reply, could not entirely agree with Mr. Johnson's explanation of the pathology of this case, for there was presence of epithelium in the interstitial parts of the tumour. He would be glad to refer it for report to the Morbid Growths Committee.

Dr. ORD exhibited a drawing showing indigo deposited naturally in the urine of a patient who had suffered for ten years with symptoms indicating enlargement of the prostate. The urine was alkaline and offensive, and contained a number of flaky masses, which, under the microscope, were found to be altered mucus, containing, embedded in them, a large number of dark-blue bodies, apparently composed of some crystalline material, partly stained by indigo, partly having indigo deposited on them. These Dr. Ord considered to be either urate or phosphate. He knew of no artificial method whereby indican present in alkaline urine might be decomposed so as to form indigo blue without inducing an acid reaction. It appeared to him that the form of the indigo was determined by the form of the substance upon which it had been deposited. He described the ordinary method of obtaining indigo from urine either in the form of a solution in chloroform, or in a film deposited on the surface of the fluid, of which he showed the microscopic appearances. If a solution of uric acid were added to the urine before performing the test, crystals of uric acid, partly stained and partly encrusted by indigo, were found at the bottom of the fluid. Epithelial cells, yeast cells, and rod-shaped bodies resembling bacteria were also found similarly stained, and coloured drawings illustrating these were shown. Occasionally hedgehog crystals of presumably uric acid were found deeply coloured. It appeared to Dr. Ord that the use of nascent indigo might possibly be of use in the staining of bacteria.—Dr. WHEATON asked if these bacteria had not the power to produce indigo. It would be desirable to cultivate them and introduce them into suitable urine to see if indigo were not produced. He had seen indigo deposited upon uric acid crystals as a result of urinary decomposition.—Professor CROOKSHANK asked if any attempt had been made to isolate and cultivate these peculiar micro-organisms.—Dr. ORD, in reply to a remark from Sir Richard Quain, said he had volatilised and deposited the crystals of indigo on glass. He had only observed bacteria in one or two out of many specimens of urine examined.

Dr. F. C. TURNER showed Microscopical Sections of the Brain from five cases of fatal Chorea in females from twelve to nineteen years of age—in one case complicated with puerperal septicæmia, in two others with albuminuria and heart disease. The sections, which were taken from the Rolandic region, all showed conspicuous swelling and opacity of certain of the large pyramidal cells in the deeper layers of the cortex. These were especially conspicuous in the first three sections, and a drawing of two of them was shown. The author, in explaining the grounds of his belief that the occurrence of an attack of acute chorea was dependent on the occurrence of a cerebral lesion of the kind shown, observed: 1. That the symptoms and course of chorea indicated a structural cortical lesion and not a nutritive derangement only, as, for example, in hysterical symptoms induced and removed at pleasure. 2. That such a dropsical swelling of the pyramidal cells of the cortex as a recoverable lesion accorded with the symptoms and course of an ordinary case of chorea and with its recognised etiological factors, while the vascular lesions to which the phenomena had been attributed did not accord with them, either pathologically or in their observed anatomical features. Any nutritive disturbance of the cerebrum must, if sufficiently severe and prolonged, induce capillary thromboses as well as lesions of the nerve cells. But lesions of the former extravascular and highly differentiated structures would occur much more readily than lesions of the latter, endowed with much greater vital resistance, especially in youth and in contact with the blood. In the specimens shown there was no evidence of vascular lesions associated with those of the nerve cells. 3 He had met with similar lesions of the nerve cells in cases of nutritive disturbances of the brain from other causes—e.g., cerebral plumbism, uræmia, &c.,—but never anything approaching the more conspicuous lesions shown. He therefore regarded these more marked lesions as distinctively choreic, magnified by the concurrent effect of other causes of systemic and cerebral nutritive disturbances,

Digitized by Google

and the series of specimens as evidence of the existence of a structural lesion of the brain, distinct if slight in degree, as the immediate cause of the phenomena of chorea in accordance with the inference deducible from those phenomena.—Dr. HALE WHITE thought that the grave diseases other than chorea with which these patients were afflicted would quite explain the conditions seen microscopically. In proof of the author's view, he should take a simple case of hemichorea and then compare the condition of the nerve cells on each side of the brain.—Dr. TURNER, in reply, considered the changes in the cerebral cells far too profound to be accounted for by the nutritive disturbances present. He believed that it was in structural aberrations in the cerebral cortex such as he had demonstrated that the true explanation of chorea was to be found.

Mr. J. R. LUNN showed a specimen of Sarcoma of the Thigh, which had been removed from the body of a girl aged sixteen. In November, 1883, the patient had been under the care of Mr. Watson Cheyne in the Paddington Green Children's Hospital. At that time the tumour was stated to have existed for two years, and the following note was taken: "On admission a fine elastic tumour was seen in Scarpa's triangle bounded above by Poupart's ligament. The femoral artery was pushed to the outer side. It was not adherent to the skin, and there were no enlarged glands. On making an exploratory incision, Mr. Watson Cheyne had found that it was a sarcoma of the ilium, and the attempt to remove it was given up." In March, 1888, the patient was admitted into the Marylebone Infirmary, under Mr. Lunn's care, with a fungating mass in Scarpa's triangle, the size of a cocoanut. There was well-marked pulsation on the outer side of the swelling, over which a loud bruit could be heard. A loud bruit could also be heard all over the cardiac area and over the large vessels. Pressure on the common femoral artery did not stop the pulsation in the tumour. Much blood was lost through oozing from the surface. No operation was permitted. In 1890 a portion of the growth was removed by Mr. Potter in the Kensington Parish Infirmary. No post-mortem examination was allowed. The author referred to a case which Dr. Bristowe published in THE LANCET in May, 1885. Dr. Bristowe had also seen the present case, and considered that the murmurs were due to the condition of the vessels of the tumour and of the arteries, not of the veins. There was no cardiac disease in Dr. Bristowe's case.

Mr. SILCOCK showed a specimen of Malignant Growth affecting the Orbit, Base of Skull, and Brain. The patient came to Moorfields Eye Hospital in 1882 with a smooth prominence above the left eyebrow, which had been growing for eighteen months. Six months later it had become much larger, and the patient had had fits of epileptic character. The left nostril was filled with growth, the left eye was proptosed, and there was left optic neuritis. Afterwards the growth increased and protruded from the nostril, the eyeball was destroyed, and the head was enormously enlarged. He died ten years after the commencement of the growth. Up to within a few weeks of death he understood remarks made to him, though he was unable to articulate himself. It was an epithelioma of typical character, probably beginning in one of the sinuses in connexion with the nose, and a considerable portion of the growth had undergone ossification.

Mr. SILCOCK also related an instance of Hereditary Sarcoma of the Eyeball in three generations. He showed a melanotic sarcoma of the eyeball of a woman aged twenty, who was admitted to Moorfields Eye Hospital in October, 1890. The growth sprang from the left half of the choroid coat of the left eye, and filled rather more than half the vitreous. The growth was of mixed spindle and round cells, and started in the outer part of the choroid. Her mother had been afflicted with an ocular tumour, similar in structure and site. She had become blind whilst pregnant with her sixth child, and the globe was excised after the birth of the seventh, which was the case recorded above. The mother's sister died, aged forty, of tumour of the breast, and she lost one eye before death. A twin sister lost an eye after a confinement, and her grandfather lost an eye from an inflammatory affection. This was probably an instance of hereditarily increased vulnerability of the tissues of the eyeball.

Dr HALE WHITE showed a specimen of Congenital Heart Disease taken from a boy aged fifteen, who had never had rheumatic fever, and who had been quite well till four months before admission, when, apparently following on influenza, he had become short of breath and œdematous. On admission he had all the signs of backward pressure. The cardiac dulness was increased; over the whole of the chest there could be heard a very loud, rasping, to-and-fro sound, closely simulating a pericardial rub. This was also audible behind, especially at the left apex. Its point of maximum intensity was in front, over the sternum, opposite the third interspace. At the necropsy, the heart was not particularly hypertrophied; at the upper part of the septum ventriculorum was an aperture between the two ventricles, and behind the right anterior aortic valve was a small aneurysm, which had burst into the right ventricle. Judging by the friction patches on the right ventricle, it appeared that the blood had flowed both from the left ventricle and from the aorta into the right ventricle.

Mr. STEPHEN PAGET showed a large Congenital Cyst from under the tongue of a little girl, a patient of Dr. Mitchell of Brockley. It had almost suffocated her at birth, protruding in a mass far out of the mouth. It had been repeatedly tapped during the first year of her life. It hung down nearly to the sternum, and was covered with a thick, harsh cuticle. The tongue was spread out over its upper and posterior aspect; the mucous membrane of the floor of the mouth was lifted up level with the teeth, and the lower jaw was twisted, flattened, and rotated outwards and downwards. The cyst was easily removed between two curved incisions, separating it from the tongue behind it and the lower jaw beneath it. The child did well, and could now almost close her mouth; the lower jaw was recovering its shape. There was no solid growth round the cyst, and it was not lined with epithelium. It was probably of the same nature as the "hydrocele of the neck" described by Mr. Hutchinson.

The following card specimens were shown:—

Dr. DAWTREY DREWITT: Case of Pseudo-hypertrophic Paralysis, with Unusual Enlargement of Muscles.

Mr. J. BLAND SUTTON: (1) Congenital Absence of Tibia; (2) Case of Duct Papilloma.

Dr. W. LAZARUS BARLOW: Aortic Aneurysm bursting into the Neck.

Mr. A. A. BROCKATT: Large Biliary Calculus.

Dr. W. LEE DICKINSON: Intra-pericardial Aneurysm, which set up Pericarditis.

Dr. NEWTON PITT: Deficiency of Diaphragm.

The annual meeting of the Society was then held. The Council reported a slight increase in the membership, and referred to the interest excited by the debate on phagocytosis. The usual hearty votes of thanks having been accorded to the retiring officers, the following were declared elected for the ensuing session, the only deviation from the Council's selection being the substitution of another name (Mr. Bowlby's) for that of the official candidate as surgical secretary. President: Sir George Murray Humphry, F.R.S. Vice-Presidents: Drs. James Frederic Goodhart, William Tennant Gairdner, Frederick William Pavy, Sidney Coupland, Sir Joseph Lister, Bart., F.R.S., and Messrs. Henry Hugh Clutton, William Watson Cheyne, Henry Trentham Butlin. Treasurer: Dr. William Cayley. Honorary Secretaries: Dr. Francis Charlewood Turner and Mr. A. Bowlby. Council: Drs. Theodore Dyke Ackland, F. G. Dawtrey Drewitt, Richard G. Hebb, David B Lees, Frederick Walker Mott, G. Newton Pitt, H. H. Tooth, Samuel West, German Sims Woodhead, and Messrs. William Henry Bennett, Thomas Colcott Fox, William Arbuthnot Lane, D'Arcy Power, Charles A. Ballance, W. Bruce Clarke, Edgar Crookshank, Walter Edmunds, R J. Godlee, William Hickman, and Samuel G. Shattock. Honorary Member: Professor Metchnikoff.

THE GERMAN HOSPITAL, DALSTON.—His Royal Highness the Duke of Cambridge occupied the chair at the anniversary dinner, held on the 10th inst., at the Hôtel Métropole. He was supported by his Excellency M. Akerman and many other official influential foreigners. His Royal Highness proposed "Prosperity to the German Hospital," and effectively urged the claims of the institution for public support. He remarked that the statistics of the patients treated during the past year showed a good record of work done. The balance sheet was on this occasion a very creditable one. A small surplus remained in hand. The year's income was £9918, and the expenditure £9300, which had enabled the treasurer to pay off a loan of £500. In the course of the evening subscriptions and donations were announced amounting to £2862.

Reviews and Notices of Books.

Elephantiasis and Allied Disorders. By JOHN MAITLAND, M.D., Surgeon-Major, Madras Medical Service. Madras: Government Press. 1891.

OWING to the prevalence of elephantiasis and other forms of filarial disease in many divisions of the Madras Presidency, the Government of Madras has wisely published this book, so that surgeons in Southern India may have their attention called to the study of these disorders, which are of special importance to those who practise in that part of the world. This small work of forty-eight pages contains an excellent account of elephantiasis and its allied diseases. The etiology, the description of the filaria sanguinis hominis, the pathology, morbid anatomy, geographical distribution, and the symptoms and diagnosis of the diseases dependent on the introduction of the filaria into the blood are most clearly and simply described. The investigations of Wucherer, Salisbury, Lewis, Bancroft, and Manson are laid under contribution in their historical sequence. Two practical points are most strongly insisted on by the author. In discussing the treatment of elephantiasis of the limbs, he absolutely condemns the operation of ligaturing the main artery, which was proposed by Carnochan in 1851, and is even now sometimes performed. He also forcibly points out the impropriety of attempting, in operating upon the scrotum, to preserve any portion of it to form a covering for the testicles, and the cases recorded by him seem to justify his opinions. The book is illustrated with nine excellent plates, and those dealing with the anatomy and the development of the filaria are especially worthy of praise. This systematic treatise brings together the various accounts of the subject that have been published since Dr. Manson's work on the "Filaria Sanguinis Hominis," and presents us with an accurate and definite picture of the disease.

Epidemics, Plagues, and Fevers; their Causes and Prevention. By the Hon. ROLLO RUSSELL. 8vo, pp. 501. London: Edward Stanford. 1892.

PROFESSEDLY written by a layman for laymen, especially those officially concerned in local health administration, and for the purpose of putting into plain language what is usually clothed in technical terminology, it would be useless to expect a perfect scientific arrangement or classification in such a work as the one before us. But surely some better arrangement of headings could be found than an alphabetical one, which leads to "measles" being sandwiched between "malaria" and "Oriental sore," and to "disinfecting" coming between "pig-keeping" and "relation of weather and season to health." Again, beginning with an account of "spreading diseases in plants and animals," in which the parasites and fungi are treated of at somewhat unequal length, the author forthwith plunges into "cholera." We may say at once that the book is nothing more than a compilation of existing knowledge, not always selected with discrimination, and often taken haphazard from opinions more or less authoritative, expressed in medical and so-called sanitary periodicals. At the same time, the industry and diligence of the author in collecting all the different facts and opinions scattered throughout the volume cannot but be commended. Under the heading of Cholera, the memoranda and conclusions of the Vienna, Brussels, and Rome Conferences are conveniently set out, and Indian experience freely quoted. There is a considerable chapter headed Consumption, and much useful information concerning the tubercle bacillus and disinfection of sputa. In this chapter much is said regarding "colds," but the author goes somewhat beyond his *métier* in vaunting the use of ammonia and eucalyptus as antidotes in the first stage of a cold. Under Diarrhœa, account is given of Ballard's researches and of the Leicester and Hull experiences.

The Diphtheria chapter is very full, and contains accounts of Power's and Klein's researches into the connexion of this disease with milk, as well as reference to its association with disease of the lower animals. American experience is quoted at great length; but the close relationship of diphtheria to school attendance does not receive the attention it deserves. With regard to influenza, Mr. Russell appears to have abandoned his theory as to its recent causation by the Chinese floods, and lays greater stress upon the conditions (telluric and human) existing at Bokhara during the feast of Radaman, and before the appearance of the disease in Russia in 1889. He quotes freely from Dr. Parsons' Report, and agrees in his view as to the spread of influenza being personal and not atmospheric. A large body of Indian experience is brought forward concerning Malaria.

The influence of schools in spreading measles is acknowledged, and the author seems to incline in favour of compulsory notification of that disease. Ballard's and Klein's researches into Epidemic Pneumonia receive due prominence. The invaluable service of muzzling in repressing rabies is acknowledged. Mr. Russell gives an account of Power's and Klein's researches into the "Hendon disease," and recognises the need of improved farm-yards and of means of detection of animal disease. We are glad to find him sound upon the subject of Vaccination; but when he says that the average duration of immunity conferred by vaccination is ten years, he evidently intends to refer to primary vaccination only; and, after commending the fulness and preciseness of the Government instructions concerning vaccination, he should not fall into the error of requiring a standard area of one square inch, when the Government is satisfied with half that size. He quotes with commendation Power's researches as to the aerial diffusion of small-pox, and is advanced enough to advise the burning of all infected air from small-pox hospitals. He emphasises the frequent association of enteric fever with milk-supplies, and draws attention again to the necessity of an improved condition of farmsteads. On the other hand, the author's reference to typhus fever is very meagre, and not up to date. Some statistics of its marvellous decline in recent years ought to have been given. The lack of proportion in treating the different subjects, which is perceptible throughout the book, is shown in the short chapter on Whooping-cough, and the inordinately long one on Yellow Fever, though the former is of far greater interest to English readers. Mr. Russell has much to say on the subjects of Susceptibility and "Immunity," not always very clearly expressed. The references to hospitals, disinfecting and quarantine, are all meagre in the extreme, and on the latter subject he affords no information as to international questions, which are of such supreme importance. Sanitary science is somewhat too abruptly summed up in the two principles of cleanliness and isolation; though as to the necessity of unity of administration, and of its corollary, a central health office, with powers similar to those of the infant Board of Agriculture, we cannot but cordially agree with him.

If the author could see fit in a new edition to arrange the subject-matter differently, and to exercise a little more judgment and discrimination with respect to the mass of quotations which form his book, we do not see why it should not become a useful work of lay reference on the subjects with which it professes to deal.

Pauperism and the Endowment of Old Age. By CHAS. BOOTH.

THE important questions discussed in Mr. Charles Booth's book upon Pauperism and the Endowment of Old Age are now sufficiently before the public to become matters of general and of animated discussion, although it must be confessed that the materials for debate are somewhat meagre and hard to discover. It is one of the conspicuous merits of a book like this that it conveys to the public mind a sense of the nature and shortcomings of the available information, and tends thereby to direct discussion along the lines that may be usefully followed. This is eminently true of the statistical material which is here treated. The great difficulty of assigning the mass of pauperism to its true causes has rarely been publicly demonstrated. The very greatness of the difficulty has a tendency to conceal it from public observation, for it has resulted in the production of official statistics of so vague and indefinite a character that the reader is easily led to suppose that nothing of interest or importance can be extracted from them, saving only the broad results which lie absolutely upon the surface. Yet, in fact, a better system would yield matter not only of the most striking significance so far as the poorest classes are themselves concerned, but also for all ranks of society, for much that is manifestly true of the pauper class is equally true, and only less manifest, of the classes above them in the social scale. For example, the causes of pauperism can be investigated with comparative ease, and it can be shown to what extent old age, disease, and vicious habits are severally responsible for destitution. As regards that class which lives upon the verge of pauperism a very small impoverishment brings them under the notice of the guardians; whereas those who enjoy a reserve of means do not reach this same level—a condition eminently favourable for observation,—unless and until the reserve is exhausted. But although less easy to observe, these mischievous forces are equally at work in the other strata of society. Sickness and drink do not put the less strain upon the resources of society because the strain is met and borne by private reserves. For example, if we take the figures which Mr. Booth has extracted from the Stepney records, we find that vicious habits, such as drink, laziness, and the like, count as principal causes of misfortune in 18 per cent. of the cases examined, sickness in something over 26 per cent., and old age in upwards of 32 per cent. To some extent these figures are, of course, characteristic of the people whose condition they portray, and to that extent they cannot be properly applied to another case. But it is nevertheless true that the parallelism is a matter of much greater importance than the disparity. The influences which cast the pauper into a state of destitution cause impoverishment, though not destitution, to his neighbours who are more well-to-do. But they are not equally mischievous. For example, old age is not a calamity to those who have the means during their prime of providing against its necessities. So, again, with sickness and with vicious habits these are probably besetments of the pauper class in a very unusual degree, but even if all possible allowance be made for such considerations we have here a most striking picture of the extent to which misfortune attends upon more or less preventible causes, and the vast field which invites the labour of the moralist and the physician.

As to the main drift of the book, we are by no means clear that Mr. Booth has made out his case. The provision of old age pensions for all old people is a measure of such vast financial proportions that it should not be seriously discussed until all reasonable alternatives have been considered. This is a view of the matter which goes much beyond the compass of the book, and it has therefore very naturally been left untreated, with the result that Mr. Booth has made nothing clear except the scheme which he favours. That is something, but it leaves even more to be desired.

OUR LIBRARY TABLE.

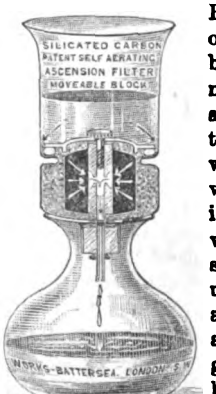
Religio Medici, and other Essays. By Sir THOMAS BROWNE. Edited, with an Introduction, by D. LLOYD ROBERTS, M.D., F.R.C.P. London: David Stott. 1892.—This exquisitely printed edition of an English classic is well worthy of its place in the dainty series to which it belongs. The enterprise of the publisher has been ably seconded by the skill and zeal of the editor, Dr. Lloyd Roberts, who, in a scholarly and finely sympathetic introduction, tells all that we require to know of the physician and philosopher who wrote the "Religio Medici," and the "Vulgar Errours." The book is one for which space could be found in the most restricted travelling-bag, and should, in fact, be the constant companion of the professional man on his holiday. It is almost as soothing to the troubled spirit as the "De Imitatione," while it stimulates thought and speculation in directions supposed to be but newly broken up by the medical pioneer. Take the beautiful essay on "Hydriotaphia or Urn Burial," for example. There we find an anticipation of the quite recent movement in favour of the reduction of the dead body to ashes, which, as Dr. Lloyd Roberts quaintly remarks, has "become a burning question in more senses than one." The most thorough-going advocate of cremation has nothing to teach Sir Thomas Browne; but, on the contrary, has much to learn from him in the solid erudition and calm ratiocination with which the whole question is considered and argued out. And all this is quite independent of the consummate merits of his style, reminding us, as few British classics can be said to do, that "the writing of English is one of the fine arts." As De Quincey asks: "When shall one hope to find music so Miltonic, an intonation of such solemn chords as are struck in the opening bar of a passage in 'Urn Burial'? What a melodious ascent, as of a prelude to some impassioned requiem breathing from the pomps of earth and from the sanctities of the grave!" But we need not dilate on the charms of one of the recognised "Dii majorum gentium" of English literature. Rather let us refer to the care with which the book has been presented to the reader, and to the general accuracy with which the frequent citations from the classics have been given. Now and again we meet with a misprint: "compana," for instance, instead of "campana"; "securisima" for "securissima." But these are rare; and does not Sir Thomas Browne himself admonish us that while "capital truths are to be narrowly eyed, collateral lapses and circumstantial deliveries are not to be too strictly sifted"? The volume is appropriately dedicated to a life-long admirer of the "Religio Medici," Sir Andrew Clark.

Analysis of Theology, Natural and Revealed. An Essay, contrasting the Pretensions of Religion and Atheism to Scientific Truth. By EDWARD GARLAND FIGG, M.D. London and Edinburgh: Williams and Norgate.—In this book we have a volume of exposition—copious, extensive, ingenious, and not wanting in erudition—of the author's theological views, which are not exactly orthodox in the ordinary sense, and on their relation to the latest findings of scientific observation. Its principal fault is an illogical and unscientific tendency to assumption. Due care is taken to expose, if possible, any gaps which may disfigure the solid highway of modern discovery; but there is no adequate sense of impropriety when the conclusions advocated by the author are reached after something of a scramble over defective premisses. The main argument contained in this work maintains the existence, apart from any material embodiment, of a spirit nature or spirit essence, which commonly operates in association with various forms

Digitized by Google

of matter, with physical forces—such as light &c.; and, finally, with what are called vital essences belonging to the animal and vegetable kingdoms, and having their representative head in Deity. The derivation of the spirit essence is unknown, but its manifestations—which afford clear evidences of design—are noticeable in every department of natural action. The chapters on the Adamic fall, regarded here as allegorically expressive of a state of spirit-purity original in nature but invaded by error and attendant evils, on the light shed by nature and instinct on the relations of God and man, and on the resurrection—that is, the resumption of its fittest bodily surroundings by a particular spirit nature,—may be noted as more especially noteworthy. The view brought forward respecting the antiquity of the world is no less ingenious than it is in the highest degree conjectural. It implies the periodic destruction and reconstruction of the earth, with a corresponding change of orbit and all other conditions. On the whole, the work might be described as a species of romance in logic, not devoid of interest, but marred by a disregard for the teaching of material facts, which may be spiritual, but is not, to our mind, convincing. The form of expression chosen, that of a dialogue, becomes tedious after a time. Now and then we meet with serious orthographic errors. Thus for "psychical" we have "psycical," "Dalphos" for "Delphi," "crysalis" for "chrysalis," &c. The discussion is heavy from the mere abundance of language, though relieved somewhat by numerous illustrative references.

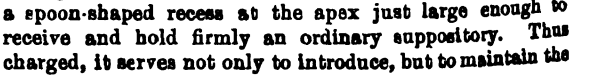
A Junior Course of Practical Zoology. By A. MILNES MARSHALL, M.D., and C. HERBERT HURST, Ph.D. Third Edition. London: Smith, Elder, and Co. 1892.—We have had occasion already to recommend this book as an excellent laboratory text-book. The appearance of a third edition in the course of a few years shows the estimation in which it is held. The authors have increased the text by about twenty pages, and have added a few new woodcuts, the chief of which are those showing the arterial and the nervous systems of scyllium canicula, and those illustrating the nervous system of the rabbit. It is one of the best of the many zoological manuals that are now accessible to the student.



Plumbing Practice. By J. WRIGHT CLARKE, Instructor in Practical Plumbing at the Polytechnic, London. London: *Engineering and Building Record* Office. 1891.—This is a practical and not a theoretical work. It is meant for the education of plumbers, but it will be useful to all whose business it is to see that plumbing is properly done—in other words, to all who are anxious about their drains. The work commences with a simple description of the principal metals used in plumbing, and their alloys, how they are obtained, how manufactured, and how utilised. The book is full of practical hints. For instance, it points out that lead pipes are often bruised by the mere transit from the place of manufacture to the place where they are to be used. Then the half- or three-quarter-inch lead pipe is sometimes bent on the spot. Such bending contracts the water-way. It is essential that the barrel of the pipe should be smooth and even throughout. If there be any difference, the pipe should be larger and not smaller at the bend. Needless to say, the art of bending pipes, forming elbows and syphons, is a fundamental question, and when not properly done causes deposits which ferment and become dangerous to health. After seeing that the pipes are perfectly round and properly bent, the joints should be inspected, and three chapters are devoted to this phase of the subject. Pipes, even when properly made, get out of shape through being suspended on hooks from walls. The subject of lining and laying sinks and cisterns is next considered, and then we approach the more familiar questions of sewers, drains, closets, sinks, ventilation of soil pipes, baths, slop-water, &c. Though these appertain to plumbing, they are subjects dealt with in every book on sanitation. Mr. Clarke gives us new instances of syphonage and many illustrations to show how traps fail to act and how their seal is destroyed by the clumsy manner in which they are adjusted. We find also a good deal of information about hot-water pipes and circulating boilers. An excellent index at the end of the volume enables the reader to refer easily to every point raised in the book. If such works were more generally studied and the lessons they teach remembered at the moment of hiring or purchasing a house, the jerry builder would fall upon hard times.

House Drainage: a Handbook for Architects and Building Inspectors. By G. A. T. MIDDLETON, Associate of the Royal Institute of British Architects, and Member of the Society of Architects, &c. London: R. T. Batsford. 1892.—This is a satisfactory book of its kind. It has the advantage of being a small book; but it sets forth in a clear and concise way the principles of the subject, and illustrates and describes the best modern appliances and methods of carrying out such principles. It is illustrated by nineteen plates and diagrams, and the text is arranged in eight chapters, embracing such subjects as are practical and useful, and about which information is most necessary.

New Inventions.



AN IMPROVED TABLE FILTER.

THE Silicated Carbon Filter Company, of Church-road, Battersea, have sent us a sample of their improved silicated carbon table filter, in which the main novelty consists in the adoption of an arrangement by which the air under the aerator cover is forced, by the weight of the water in the upper vessel, through the filtering medium itself. Thus the impregnation of the water with air is to a certain extent secured. As we have frequently urged, aeration is just as important a factor in the purification of water as is efficient filtration, and we are glad to find that makers of filters have of late given their attention to this very important point.

NEW SUPPOSITORY INTRODUCER.

THIS instrument is very simple in construction, being merely a solid vulcanite bar conveniently curved, and having a spoon-shaped recess at the apex just large enough to receive and hold firmly an ordinary suppository. Thus charged, it serves not only to introduce, but to maintain the

suppository in contact with the surface it is desired to affect during solution, and afterwards of absorption or continued application, as may be desired. The instrument has been made for me by Messrs. John Richardson and Co., Leicester, Limited, and answers perfectly.

THE LANCET.

LONDON: SATURDAY, MAY 21, 1892.

THE May meeting of the Medical Council will be inaugurated on Tuesday next, at two o'clock, with the President's address. In the absence of the official programme it is not easy to forecast the exact nature of the discussions; but the general drift of them may be surmised. There will be some noticeable differences in the *personnel* of the Council. One of them will be caused by the retirement of Professor STRUTHERS, and in his place Dr. ANGUS FRASER will represent the University of Aberdeen for the next five years. Dr. STRUTHERS will be much missed. He was not always in debate a master of the art of making his opposition pleasant. But he did much hard and valuable work in the Council, especially as chairman of the Education Committee, and he spoke with the authority of a large experience and a rare enthusiasm as an anatomical teacher. The University of Durham, in consequence of the death of Dr. GEORGE HEATH, will now be represented by Dr. PHILIPSON of Newcastle-on-Tyne. The newly elected Direct Representatives, having previously served in this capacity, should bring to the Council the advantage of some acquaintance with its methods and a large knowledge of the views of the profession. It is customary to regard the May meeting of the Council as set apart more especially for the discussion of questions of medical education. And in the light of the great extension of time that has been given to the medical curriculum and the great additional opportunities which such an extension affords to medical teachers, it is reasonable to think that some discussion will be devoted to securing that this extension shall be put to the best uses. But the Council will not have at its approaching meeting the full materials at its disposal to permit of exhaustive treatment of the subject. The term of five years only now becomes obligatory. It applies to those alone who commenced their medical studies after Jan. 1st, 1892. In the first instance it is the duty of the medical authorities to say how this additional year is to be used. They are understood to be diligently considering this question. They have been requested by the Medical Council to forward to the registrar, at the end of the year 1892, a copy of their regulations, in the form in which they then stand, and under which they confer qualifications in medicine, surgery, and midwifery. The Council, and especially its Education Committee, are responsible for this eventful change in the conditions of medical education, and it is to be hoped that the coming meeting will give evidence that the Council is alive to its responsibility on this subject and is resolved to make its influence felt. It is easy enough for the Council to toss a great resolution like this to the bodies to be worried by them, as dogs worry a bone, all fighting for their own interests, and all alike ready to add to the existing agonies of medical education and examination; but the Council is expected to follow up its resolutions and to see that the spirit and purpose of them are fulfilled. This important addition to the burdens of the student and his parents arose out of proved defects in practical education inseparable from a too theoretical way of teaching. The Council itself has clearly indicated that the additional teaching that is to be imposed shall be clinical and practical in its character. It will doubtless ascertain by its inspection and its inquiries how far this essential object is being secured. There is one thing almost more important in regard to which we may hope, at the approaching meeting, to receive some light. Last year the Secretary for War took the Council into consultation on the defects of preliminary education shown in candidates for the medical service of the army. The Council passed a resolution asking the bodies to take note of instances of candidates in whose examinations evidence of gross defect in general education occurred, and of the bodies by which such candidates had been passed in preliminary subjects, and to report to the registrar of the Council. We shall see if any light is thrown by this means on a subject which deeply affects the character and standing of the medical profession. It is lamentable to see the failures of some students in their after career. It would be true kindness to reveal their unfitness to them at the preliminary stage of their course. Other questions affecting the bodies, or interesting to the profession, but of a more or less general character, are likely to arise. The Council, when discussing this question of preliminary education, expressed regret and disapproval of the medical examining bodies continuing, as in the case of the Society of Apothecaries, to examine in general education. We may hear whether such bodies are prepared to abandon this part of their work. But we shall be better prepared to judge them when we know what bodies pass men whose spelling is so faulty that the War Office makes it a ground for inquiry. It may turn out that general educational bodies are as lax in this matter as others.

Although at the May meeting the Council is supposed to be occupied with high educational matters, it will not be able to exclude more painful duties. We understand that there are several cases in which charges against practitioners of employing unqualified assistants in a way of which the Council has repeatedly and significantly expressed its strong disapproval will have to be investigated.

THE debate upon renal dropsy at the Royal Medical and Chirurgical Society is to be reckoned amongst the chief features of medical interest of the year. The discussion upon "immunity" recently raised at the Pathological Society, from the greater novelty of the subject, naturally attracted a larger audience; but the speakers represented the practical pioneers of pathology and bacteriology, while the debate upon the every-day subject of renal dropsy was necessarily carried along the more uncertain ground of deductions drawn mainly from clinical observations, and many of those who spoke merely gave their own interpretation of facts which were not in dispute. It is interesting, though by no means surprising, to find that this subject

Digitized by Google

could furnish material not only for a lengthy paper from Dr. DICKINSON, but also for a discussion which consumed the available limits of two meetings, and gave evidence of great divergence of opinion amongst many physicians whose position and clinical experience entitle their views to respectful consideration.

Such differences of opinion were apparently to a large extent the result of the attitude assumed by Dr. DICKINSON towards the part played by the capillaries in acute and chronic forms of dropsy dependent upon acute or chronic kidney disease. His ideas were in the main foreshadowed in his Harveian Oration. They were then objected to in certain quarters, and in answer to the challenge he promised to present them more fully in his communication to the Royal Medical and Chirurgical Society. In his preliminary remarks he traced the various agencies under which fluids pass through the capillary walls, laying especial stress upon filtration or transudation under pressure. Step by step he elaborated this idea, and at the same time gave his reasons for considering that osmosis was an insufficient and unsatisfactory explanation; indeed, at a later stage he did not hesitate to say that the theory of osmosis "was dead—irrevocably and thoroughly dead." Having thus gone a certain distance on lines of destructive criticism, he threw out the idea that the association of œdema and increase of tension could be attributed to some condition of the capillaries due to abnormality of blood, which both hinders its passage and promotes transudation. Turning to chronic conditions, he maintained that the associated cardio-vascular change is the direct antagonist of dropsy, and he adduced an array of cases, tables, and cardiac diagrams in support of this contention. By ingeniously contrasting the conditions met with in acute nephritis with those of granular kidney, an air of greater probability was afforded; since with the former there is much dropsy with slight hypertrophy, while with the latter there is much hypertrophy with little dropsy until towards the fatal termination, when dilatation of the heart is accompanied by an increase of dropsy. These facts, however, have previously been claimed (and were claimed again in the course of the discussion) in support of the older theory of the conservative hypertrophy of the arterioles. Dr. DICKINSON, while he admits the truth of Dr. GEORGE JOHNSON'S description of the muscular hypertrophy of the arterioles, nevertheless believes that the observations of SIR WILLIAM GULL and Dr. GAWEN SUTTON upon fibroid thickening were equally true; but having gone so far with previous workers he parts company with them, and endeavours to refer all questions of obstruction to the circulation and consequent transudation to changes in the capillaries rather than to changes in the arterioles, even though the nature of the capillary obstruction must be left undeclared. His final conclusions are peculiarly noteworthy, since they comprise his views not only upon renal but also upon cardiac dropsy. "Under heart disease there is diminished absorption without any presumption of increased exudation, or not to any important extent. Under kidney disease there is increased exudation without any necessary or constant diminution of absorption. Both are essentially connected with modifications of blood-pressure—in one from obvious obstruction to the venous return; in the other from some presumably obstructive condition of the capillaries, which is attended with enhanced exudation from them, and associated with increased pressure within the arterial system."

Dr. GEORGE JOHNSON, whose views upon the stopcock action of the arterioles are so well known that they require no restatement here, once more raised his voice in support of his doctrine that the arterioles could impede or arrest the circulation, and maintained that there was no evidence that the capillaries possessed a similar power. He thought there was no evidence of an increase of capillary pressure in renal dropsy, and he inclined to the idea that renal dropsy might be best explained as a vital act of the endothelium excited to eliminate certain noxious solids and fluids from the blood. Dr. PYE-SMITH dwelt upon the importance of distinguishing two forms of dropsy with renal disease—a late "hydraulic" variety, which was purely cardiac in origin, though associated with granular kidney; and an early or renal variety, found with the large red or the large white kidney. So far his views appeared to be completely in harmony with those of Dr. DICKINSON, and indeed of most subsequent speakers; but in his explanation of the renal variety he stood alone in regarding it as possibly an inflammatory effusion, and not true dropsy, the seat of the inflammatory changes lying in the connective tissues. The cardiac origin of the late dropsy of renal disease received the support of Dr. DOUGLAS POWELL, who also thought that the high tension pulse of kidney disease had nothing to do with the production of dropsy. Dr. BROADBENT similarly accepted the explanation of the dropsy of old-standing chronic Bright's disease, and, without definitely accepting Dr. DICKINSON'S explanation, thought that it was in all probability the most correct theory yet formulated. Dr. SANSOM argued in favour of auto-intoxication, and referred to the late Dr. WOOLDRIDGE'S experiments with the injections of toxines into the blood. The influence of uric acid upon the contraction of arterioles was also mentioned, and an attempt was made to show that the more or less rival theories of Dr. DICKINSON and Dr. JOHNSON were perhaps not wholly irreconcilable. An unexpected jubilant tone pervaded Dr. DICKINSON'S reply, and he naturally adhered to his view that the capillaries were the primary seat of the obstruction, whatever might subsequently take place in the arterioles. His belief in his theory was so strong that he thanked Dr. BROADBENT, not for supporting him, but for "supporting the truth."

At the conclusion of the debate the President, Sir ANDREW CLARK, stated that it had originally been his intention to give a short summary of the discussion, but he shrank from the task of being drawn into expressing any general conclusion upon the various views expressed. Admitting the great interest of the debate, we also may perhaps be pardoned for thinking that a final solution has not yet been reached.

IT has been our pleasant duty, as well as our privilege, to record from time to time some very creditable deeds on the part of medical officers of the military services. It is also not long ago that the name of GRANT of Thobal

Digitized by Google

fame was uppermost in men's minds, and now the self-reliance and pluck displayed by a very young officer of the Royal Artillery—Lieutenant MACMUNN—have attracted attention. The great training ground of India has afforded them, as it has done to many of our officers, an opportunity for the manifestation of qualities which might otherwise have never been exhibited at all. Some of these various instances have been illustrations of what is commonly called "pluck," some of devotion to a sense of duty, some of enterprise, fortitude, or what not,—for courage takes a variety of forms, and is of different qualities. It has been the frequent theme of poets, philosophers, and essayists. In so far as physical courage is the outcome of physical energy—of constitution and temperament, for example—it is physiological in its nature and origin. It is often the resultant of a young and vigorous vitality, prodigal of life, in which the whole animal machinery is adjusted in harmonious action and toned with the right sort of temperament. The nervous centres are irrigated by blood streams pumped into them by a vigorous heart; the tissues flow with healthful sap, and the will moves straight along the highway to action, without lingering in any by-path, to be "sicklied o'er with the pale cast of thought." Men of this stamp seem to be without any sense of fear whatever. Deeds of daring are to them but a pleasurable excitement; risk and danger simply add a *soupçon* of exhilaration to the work. This is a form of animal courage, of an eager and impetuous sort for the most part, born in certain men and races. It is a terrible force in attack, but liable to panic, and unstable in so far as it is influenced by fluctuations in health. There is another type, the antithesis of this, in which great courage is manifested by those who are popularly styled highly-strung nervous men. Under excitement, or when suddenly called upon to face great danger, and under states of nerve tension, such men become cool, deliberate, and altogether regardless of fear. They are frequently men of marvellous resolution. The pallid face and apparent manifestations of "funk" are really but an outward sign of the inward working of the physiological mechanism. They answer to NAPOLEON'S two o'clock in the morning courage. We once knew a determined dog that went out of his own accord and doggedly laid himself in wait at the corner of a street for his enemy. He was in a nervous quiver from the tip of his nose to the tip of his tail. Nevertheless, the other dog found him resolute enough. But there are many types—too numerous to mention—such as the intellectual and moral kinds of courage, and that intimately associated with the phlegmatic temperament, in which doggedness of purpose and insensibility to emotion and pain are the main elements.

Courage and fortitude are two very different things. A man may exhibit great pluck and "nerve" in facing an unexpected danger who would be crumpled up by the slow fire of affliction, or worn out by the friction of continued difficulties, or stunned by the impact of repeated blows. The ardour and élan of young troops will impel them to attack at any odds, but they are liable to lose their heads in surprises, and to be influenced by the contagion of fear and panic from the other hand, although the older and more [illegible] seem about attacking, it is uncommonly hard to drive him from his purpose when once he begins. The physical courage, which in the main depends upon physical qualities, and is fortified by discipline, is, we imagine, rather likely to be weakened by education and thoughtfulness; and it becomes a nice point, to determine whether the increase of the soldier's efficiency in one direction, by education and the exercise of his intelligence, may not be diminished in another, when troops are called upon to undertake the self-sacrificing duty of a highly hazardous or impossible service for some great, but to them unknown, strategical gain. It requires the absolute obedience of an unreasoning mind to attempt the impossible for an unknown object. Courage under such circumstances is the fruit of the tree of ignorance, and not of knowledge. Fearlessness is often the result of ignorance of danger, as in the case of children and some semi-civilised nations. The bravery of some men is intimately associated with their vanity. Apart from vanity they are cowards. They will do anything so long as it is in the presence of spectators or in the expectation of fame and praise, just as there are some men whose bravery may always be counted on regardless of praise or blame, and who would be heroes in the dark. Although courage is born in a man there are some excellent substitutes for it, such as the force of fanatic zeal and fatalistic belief; and it can be wonderfully developed—it may almost be said to be created—by training and by familiarity with danger, provided it be not a danger that dominates the imagination with a feeling of powerlessness. BUCKLE was right in saying that impressions made by the forces of nature developed fear and superstition, and that men do not grow braver by living in a land of earthquakes. The courage of even the bravest man is not any fixed quantity. It is not always the same by any means. It depends greatly upon varying but unrecognised states of health, for one thing; and for another, perfectly new kinds of experience will sometimes impress the imagination and instil timidity: the boldest cross-country rider may turn pale in a boat. One of the great merits of RUDYARD KIPLING'S graphic sketches consists in this: it has raised our estimation of the British soldier, who undoubtedly possesses, with much that is coarse and brutal, some noble qualities. He is patient, brave, dogged and determined, generous, and the least vindictive of men; and TOMMY ATKINS is not given to hurting a dog or a little child. But after all is said and done, courageous men are, like poets, born, not made. Take the latest instance, Lieut. MACMUNN. Accompanied by fourteen Goorkhas and some Panthay mule-drivers who had charge of a convoy of some commissariat mules, he marched twenty-four miles through a hostile country subjected to the fire of a concealed and stockaded enemy. He was little more than a boy, and alone with troops he had never seen before. He pushed on to Sodan, whither he was going with some rum for the little garrison there. He "rushed" several stockades and crossed a river under fire, having by his self-reliant leadership impressed some of the bravest troops in the world—the Ghoorkhas—with admiration of his pluck. The GRANTS and MACMUNNS of our public schools leave England with the corners of the British flag grasped unconsciously in their hands, and spread it over the four quarters of the globe. It is to them, and men like them, that we owe our national name. A handful of boys is shipped to Africa or

Digitized by Google

Egypt, to the Black Mountains or Burmah—no matter where; and, as long as they can stand, we may depend on them to push on. Bad health they merely look upon as bad luck; and, having denounced the heat, they do their utmost to forget it in some form of sport—of which the best is probably, in their opinion, fighting. Anyone who knows Burmah, for example, knows this class of man; he laughs at fever until smitten by it, and laughs again when he recovers. He goes sadly into hospital, but comes out of it quite cheerful when cured, and hopes he has not lost his opportunity. His soul, in times of peace, is given to his gun and polo pony; in times of strife, to getting these to the scene of it; and, having got there, to getting further. So the tentacles of British rule are pushed out, not to be withdrawn. So England has become an empire; and, while force of will and pluck endure, she will extend her boundaries from sea to sea and land to land. It may seem vainglorious to say so, but no other nation works and plays as England does on foreign soil; no other nation kicks a football in the Afghan Hills, or wields a cricket bat in Upper Burmah. No other nation persistently defies climate and disease, and labours under a tropical sun or amidst icebergs with the same indomitable perseverance, scornful in the matter of difficulty and unconscious of defeat. Any Englishman with work to do will do it if he can or drop. Thousands upon thousands of them do drop, but thousands more press on. The giant in the fable who "smelt the blood of an Englishman" was doubtless allegorical and certainly ubiquitous. The motto of the regiment to which MACMUNN belongs, and the nature of the nation of which he is a son, are both of them "ubique."

THE ordinances made by the Commission appointed by the Scottish Universities Act of 1889 have now been issued in their final form, and were brought before the House of Commons on the 10th inst. Notwithstanding the opposition of Mr. HALDANE, Dr. CLARK, and Sir G. TREVELYAN, they passed the House by a large majority of votes, having been supported by the able and thorough advocacy of Professor JEBB and Sir H. ROSCOE. We referred last week to the unsatisfactory position in which the subject of *materia medica* is placed by the ordinances dealing with the study of medicine, but this was a merely incidental question raised by Dr. FARQUHARSON. The main discussion was very important because it practically decided whether "extra-muralism" was to be introduced into the other faculties as well as into the Faculty of Medicine, in which everyone acknowledged it had worked admirably and with marked advantage to the teachers as well as to the students. Professor JEBB pointed out most clearly the differences in aim between the education of the student in arts and of his brother student in medicine. The study of medicine, he said, is a professional study, and the fitness of the medical student for the practice of his profession can be tested by a proper series of examinations; and, provided he has the theoretical and practical knowledge, it is not material where this has been acquired. Such is the usual argument; but, if this be everything, why should certificates of attendance on lectures and hospital practice be required by all examining bodies? Even such a purely examining board as the University of London dares not in medical subjects trust to examination tests only, but demands evidence of a very strict and thorough course of medical training. In fact, both training and examining are essential; indeed, we think too much stress is laid by many bodies on examination tests, which we know to be not always judicious, occasionally capricious, and in nearly every case, for many reasons, necessarily incomplete. Whilst other practical and technical branches of science can also be thoroughly tested, literature and arts come into a different category. In these it is the function of the teacher to educate the mind, and his teaching should be of quite a different type to that of those who would simply give instruction to assist a student through an examination, or who are obliged to lay special stress on those technical details which necessarily must be of primary importance to everyone whose object in life is to gain entrance into, and practise the arts appertaining to, a technical profession. It has been particularly creditable to the Scotch Universities that the teaching of their best professors in literature and arts has never been unduly cramped or fettered habitually by a regard to mere examinations. A very different course has been followed by the University of London, and private study of given works, aided even by "correspondence crammers," has taken the place of the higher University teaching. A candidate for its B.A. degree is no longer judiciously taught step by step the classical and modern languages as a University teacher would educate him, but his attention is assiduously directed to a set textbook or to a given author, and he learns little beyond these, because nothing else pays at the examination. If the Scottish Universities were to recognise teaching in arts otherwise than by the professors or lecturers under their control, they could not restrict extra-mural teachers to the great centres, but would have to include other teachers residing all over the kingdom, for many of these would be equally competent to teach, and the Universities would then become mere examining boards. Their great functions as teaching bodies of the highest rank would soon be gone, and the students would no longer take the trouble to go to the Universities, but would endeavour to pass the necessary examinations by the aid of local tuition. In short, the whole of the Scottish University system, with all its traditions and merits, would be destroyed. We are pleased to see that the Commission has determined on the appointment of additional lecturers and practical assistants in many subjects; a properly fixed payment for these lecturers should be made from the financial chest of the University. Such improvements are urgently needed, and the University Court, not the Senatus, should have the control of the finances. In such matters, and in other details of less importance, we would strongly support the reforming party; but we cannot ignore the many advantages in the new ordinances, or unreservedly support an opposition which, because of some defects not being removed, might have deferred all University reform to a distant and uncertain future. The position of the question of the higher education in London at the present

Digitized by Google

moment is surely a sufficient warning to injudicious and extreme partisans, content with nothing less than the adoption of every minute detail in their own schemes of University reform.

Annotations.

"Ne quid nimis."

THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS AND THE FELLOWS OF THE COLLEGE.

WHEN the Council of the Royal College of Surgeons of England appointed a committee, at its meeting in March, to consider whether any, and if so what, further advantages could be extended to the Fellows, it was generally thought that at length the often-expressed wishes of the Fellows for a substantial voice in the affairs of the College were about to be fulfilled. So satisfied were some of the members of the Association of Fellows that they began to talk about dissolving the Association in the near future. All ideas of this kind must be absolutely abandoned, for it is probable that a great deal more pressure will have to be brought to bear upon the Council before any substantial concession is made even to the Fellows, to say nothing of the Members. The Committee of the Association of Fellows, hearing of the action of the Council, suggested that a deputation from the Association should be asked to meet the Committee, in order to set forth the views of the Association. To this request the Council has returned the following reply:—"That the Council do not consider it expedient that their Committee should receive any deputation, but that the Council will be glad to receive any written communication from any Fellow or Fellows of the College as to any further advantages, *not involving changes in the Charters and By-laws*, that might be extended to the Fellows." The words in italics clearly show that the Committee has not been allowed a free hand in regard to the recommendation of privileges to be granted to the Fellows. The election of the President of the College by the Fellows, which so many Fellows desire to see accorded to them, and the simplification of the present method of distributing and receiving voting papers in the elections for the Council, cannot be conceded without changes either in the Charters or By-laws, or both; so that even the consideration of these important measures must be set aside. In the same spirit, no doubt, every obstacle will probably be raised to making the consultation of the Fellows at separate meetings real and efficient. For the last eight years the Association has persevered, and it is now beginning to reap the fruits of its labours. That some concession will be recommended by the Committee of Council we do not doubt; but of this we are equally certain, that it will fall short of what the Fellows desire, and what they ought to have. Let it be remembered that all concessions which are not confirmed by Charter and By-laws must prove illusory. They will be revokable at the pleasure of the Council, and, like Dead Sea fruits, they may tempt the eye, but they will be liable to turn to ashes on the lips. Until the concessions are made real, substantial, and lasting by the sanction of the Home Secretary and of the Crown, let no thought of dissolution enter again into the minds of the Committee of the Association of Fellows, but let them redouble their exertions and fight the battle till the victory is [illegible]

WESTMINSTER SCHOOL.

WE understand that five cases of scarlet fever broke out in one of the boarding houses between the 7th and the 10th of this month (inclusive), all of which were removed to the sanatorium. The cases were thus isolated, and it was hoped that the outbreak would end here, and that the work of the school might still go on. But on the 12th, 13th, and 14th four additional cases occurred in the same boarding-house. There have been also two other cases of scarlet fever among the home boarders. One was a day boarder at the boarding-house above referred to, and formed one of the first batch; the other case has arisen since the dispersal of the school. After consultation, it was thought advisable to close the school, and to take the opportunity of thoroughly cleansing and disinfecting the whole place. It was believed the contagion was still limited to the one house. The cleansing and disinfecting are now in progress, and Dr. Bristowe, the medical officer, has every reason to believe that the school may safely reassemble in the course of two or three weeks. The primary source of infection has not been ascertained; but it is clear that the first group of patients must all have contracted it from the same source. The later cases no doubt caught the disease from the earlier ones. The outbreak has been of a remarkably mild type. Not one of the cases has given cause for any anxiety, and most of them have been so slight that, but for the light thrown upon them by other cases, they might easily have been overlooked. It is but right to add that the school has enjoyed a remarkable immunity from infectious disease, and that this is the only term for over twenty-six years in which it has been necessary to disperse the boys.

THE RECENT ELECTION OF SECRETARY AT THE PATHOLOGICAL SOCIETY.

AT the annual general meetings of our learned Societies it is usual for the Council to put forward a list of names of candidates for the various offices, the individuals nominated being carefully selected after due consideration of their merits. This, of course, does not bind the Society at large to abide by the choice of the Council; and we should be the last to advocate that the power of ultimate selection should be taken from the general body of the members. But so much confidence has been hitherto invariably, and we think rightly, placed in the discretion of the Councils of the Societies that the ballot has come to be regarded by most of the members as a mere matter of form, and only a tithe of them usually go through the formality of recording their votes. Under these circumstances it is quite possible for a small clique to take advantage of the confidence of the Society and use for their own ends the prevailing laxity as to voting. In this connexion we regret to have to allude to what occurred at the last meeting of the Pathological Society. The Council, in the ordinary course, had asked a surgeon to allow himself to be nominated for the post of surgical secretary, and his name appeared in due course on the ballot-sheet. Certain members of the Society connected with a particular hospital thought that one of their own staff should be appointed to the post, and so they came down *silently* and voted in a body. They represented but a small proportion of the meeting—an insignificant minority; for the greater number of members present were contented to believe that the nominees of the Council were safe. We can only conclude our remarks on this unpleasant incident by recording the surprised and indignant feeling of the meeting as expressed afterwards by groups of its members who discussed the subject. The moral to be drawn from the occurrence is obvious. Every member of a learned society who [illegible]

Digitized by Google

to preserve the traditions of the profession in these matters and uphold the power of the Council should take care to perform the trivial and simple, yet all-important, duty of recording his vote on these occasions; and it is well worth consideration by the Society whether any additional nominations to those on the circulated list should not be made sufficiently public to enable all to express an opinion on the relative claims of candidates.

SUSPENSION OF A POOR-LAW MEDICAL OFFICER.

WE gather from the *Cheltenham Examiner* that Mr. Walters, one of the district medical officers of that town, has been suspended from his duties for not visiting without an order the child of a person receiving parish relief. We consider that Mr. Walters has been badly treated, as he did nothing legally wrong, and we strongly advise him to appeal to the Local Government Board. If the rule relating to the granting of orders be ignored by parochial medical officers, appointments of that nature will not be worth having, and it will tend still more to increase the erroneous impression that parochial medical officers are at the beck and call of anyone choosing to send for them. We may mention that Mr. Walters's legal advisers, and also the clerk to the guardians, considered he had acted according to the Consolidated Orders.

THE IDEAL CONSULTANT.

WHEN, nearly a generation ago, Sir Henry Acland in a memorable publication introduced the Oxford Museum to the academic world and foreshadowed the benefits it would bring to liberal culture as a whole, and more particularly to that of the physician, he gave a picture of the "ideal consultant" which, if more comprehensive than detailed, may be said to come as near perfection as such compendious characterisations are capable of reaching. In a quotation from Suidas he adduced the answer of the consultant Trophilus, when asked to define the all-accomplished physician:—"It is he," said Trophilus, "who is able to distinguish between what can and what can *not* be done." This definition may be said to cover every requisite in the medical adviser in whatever circumstances the exigences of his calling may place him; but it does not, of course, enter into native aptitudes, or acquired dexterities, or in short into the *ensemble* of qualifications which combine in the physican who is ever ready and never at fault. One definition, or rather indication, of what the successful consultant really is was incidentally given some years ago, by an outsider, in a strictly professional controversy—a definition which embodies the lay belief in the personal power of the physician apart from what special discipline can make him. "A great physician," he said, "is a great artist." This also is true, and will be found on closer analysis to explain the extraordinary success of practitioners whose book-learning or laboratory training is notoriously far inferior to their power in diagnosis and their success in treatment. The Athenian intellect at its best and in its most characteristic mood—essentially artistic as it was—seemed to fulfil the requisites which from time to time attain medical embodiment in a Sydenham, or, to come within our own day, in a Bamberger, whom, *consensu omnium*, each morning's encounter with cases of every kind in the Vienna wards found seldom or never at a disadvantage. That intellect, in its combination of nimbleness with strength, of centripetal insight with sense of proportion and judicial balance, has been described for all time by Thucydides in his wonderful picture of Themistocles. He dwells on the native understanding of "that Athenian of Athenians"; on his power, without previous information or after-thought, with, indeed, the briefest consideration of the problem in hand, to form a picture in his mind of what it really implied and of what its solution would yield—diagnosis, in short, and prognosis, almost improvised as to readiness; and again, when the problem admitted of only an approximate or provisional solution he could—"this way and that dividing the swift mind"—alight on the better and avoid the worse interpretation, even in the absence of previous prompting or of the data indispensable for less artistic minds. The whole passage (*Thuc*, i., 138) is well worth pondering in this connexion, and will serve to explain how the idea of an "artist" dominates the popular conception of the consummate physician—as is, indeed, involved in the German word "Arzt," which Becker rightly derives from the Low Latin "artista." Noteworthy, too, is the fact that the intellect here typified is always genial, always repays the confidence it invites by possessing the patient with the belief that his malady is indeed of personal interest to his adviser, who considers, and pronounces, and prescribes as if he were in the other's place. That is what Celsus means when he talks of the "hilaris vultus" of the ideal consultant—what Horace implies by the "deformis ægrimoniæ dulcibus alloquiis." The character thus equipped by nature becomes more and more developed by experience, till, as statesmen and men of letters, and indeed the moral and intellectual grandees of every age, combine in attesting, humanity appears in no more admirable or lovable form than in that of the "ideal consultant."

THE JOURNAL OF PATHOLOGY.

THE publication of the first number of the new *Journal of Pathology*, of which Dr. Sims Woodhead is editor, is an event which requires a few words of special notice; for, notwithstanding the large number of active workers in this field, they have hitherto been content to record their observations in the Transactions of societies and the columns of the general medical press. But we gladly welcome a special medium for their publication, which has long been needed in this country. The journal is apparently planned upon much the same lines as the now well-established *Journal of Physiology*, and we have no doubt it will attract many excellent contributions. We have before us the advance sheets of the first issue, and can testify to the variety and value of the papers it contains. The first place is rightly given to an article by the foremost pathologist of our generation, Professor Virchow, who writes upon Transformation and Descent with the lucidity that characterises all his work. He expounds once more the nexus between physiological and pathological processes by reference to the cell doctrine, explains how metaplasia is brought about, and restates the argument in support of tissue proliferation in relation to new formations. Dr. Metchnikoff of Paris contributes a paper on the Aqueous Humour in Relation to Micro-organisms and Immunity, and proves from his observations that the aqueous humour is not only "a good cultivating medium for micro-organisms in general, but also for the special microbe to which the animal from which the aqueous tumour is taken is immune." Although occasionally the aqueous humour has bactericidal properties, these stand in no relation to the immunity of the animal concerned. Dr. Sidney Martin follows with an interesting account of a Chemical Examination of a case of Anthrax in Man. An important Study of Cerebro-spinal Pressure is afforded by Mr. H. Percy Dean, based on clinical and experimental observations; and Dr. James Mackenzie of Burnley deals with the question of Venous Pulsations, and describes a ready method for their record. His paper is enhanced by detailed accounts of cases, and the conditions under which the phenomena occur are fully stated. The waves described and graphically figured are shown to be

both of auricular and ventricular origin—in relative predominance according to the extent of the cardiac defect present. Professor Halliburton records his later observations on Mucin in Myxœdema; in only one case (furnished by Dr. Oliver) did the amount of that substance in the heart tendons much exceed the average normal percentage. An abstract of Dr. Grawitz's article on Hæmorrhagic Infarcts of the Lung, contributed to the Virchow "Festschrift" follows, the conclusion being that "there is no connexion between infarction and embolism, but rather that infarction is the result of chronic bronchitis combined with cardiac weakness." Dr. Alex. Miles writes on the Microscopic Pathology of Cerebral Traumatism, and Dr. Herbert Spencer on Hæmatoma of the Sterno-mastoid Muscle in New-born Children; Mr. Andrew Pringle has a note on Paraffin Infiltration by Exhaustion, and Dr. A. E. Wright on the Relations between Plasma and Serum and upon a Modification in the Method of Obtaining Serum.

THE VITALINE CRAZE.

To call it consternation is not too strong a term; for although we do not accredit the statement that ten thousand people in Russia have received injections of the stuff "vitaline," there is without doubt a panic on the subject of this injection—this most absurd so-styled "rejuvenator" of old idiots and antidotal preserver of young ones. The story of the "discovery" of this "new remedy" is an old story revived. A wanderer from his native land, this time one Gatchkowsky, an engineer, was sent on his own business into the Trans-Caspian territory, and there, amongst a primitive people, he heard of a new specific. "A Chinese *savant*" revealed to him the particulars of a miraculous compound medicine which, being instilled into the blood of man, would cure everything: it was more than a mere panacea; it was a "rejuvenator," a curer of such fatal diseases as consumption of the lungs without fail. All previous wonders were to be surpassed by it, and the scientific world was once more to be set in commotion by a discovery that should show how natural law in disease could be overthrown in wholesale fashion. For a time—happily short, yet long enough—the new practice made its way, and we are told the regular practitioners of medicine in St. Petersburg were dumbfoundered by the presence of the "tide of fashion and of favour" that set in. To some invalids, real or supposed, the "vitaline" was administered by injection subcutaneously; to others it was administered internally. Prices for the remedy and its application varied; the rich paid largest fees, but the poor also paid, and some of them also largely. The Czar himself was counselled—by whom is not known, but we should suppose not by any authorised medical adviser—to let his son, the Grand Duke George, undergo the treatment. At last a somewhat less important man, but still one of great importance, was subjected to the remedy, and he, General Gresser, the Prefect of St. Petersburg, and one of the firmest and shrewdest of the guardians of the imperial power, was led to submit himself to the operation, and by the submission sacrificed his life. How, precisely, the sacrifice was brought about we have as yet no satisfactory details. The discoverer of "vitaline" turned round in his defence from the sublime to the ridiculous. The omnipotent remedy at once diminished from its potency into a mere mixture of borax and glycerine—a harmless mixture for good or for evil. If death resulted from the use of it, a dirty syringe used for the injection must have been the true cause; but M. Gatchkowsky, having made a clean breast of his discovery, will practise the art of cure no more; and if he be not, in the panic, charged with political offence and of systematically poisoning the Prefect, he is fortunate. The history of this latest blast of quackery recalls some of olden times which it has been the duty of THE LANCET to expose and trample out. The case of the notorious St. John Long comes at once to mind. In this case the results which followed the practice of the astute quack were practically the same as those we have just witnessed. What is more, the secret, which Long sold, as was reported for £3000 to a lady of fashion, turned out, in the end, to be no secret at all. The element of treatment was counter-irritation, and the vaunted composition employed as a liniment was nothing more and nothing less than spirit of turpentine and strong acetic acid. One day the famous nostrum went wrong in its action; it caused, or was accused of causing, a diffuse cellulitis in an unfortunate victim, and then not only was its fate sealed, but in defence the secret was exploded in proof of its harmlessness and its perfect simplicity. Against this specimen of quackery the founder of THE LANCET fought tooth and nail. He neither hesitated nor paused until the mischievous practice was expelled for good. In this fight, moreover, he had not the whole voice of the profession with him. On the contrary, one man in the profession stood by the delusion to the last, and vainly maintained his advocacy of it after the bubble had burst and its inventor with it. It is our business still to expose, and protest against, these frauds on humanity, exploited as they are at the risk of human suffering and death.

PRESENTATION TO DR. HOLMAN.

WE have been favoured by the *Surrey Leader* with an account of an event, interesting from its nature to the profession of medicine, and suggestive of the high point which it is possible for a general practitioner to attain in the esteem, respect, and affection of those who are at once his patients and his neighbours:—Dr. Constantine Holman, J.P., of Reigate, was, on Saturday, the 14th inst., presented at the Reigate Town Hall with a massive silver bowl, four silver baskets (engraved with the crest of the recipient), and a cheque for £130 (the balance of the Testimonial Fund). Dr. Holman has been in practice at Reigate for forty years, and during the greater part of that time he has been the chief partner in the firm known until recently as Holman, Hallowes, Walters, and Berridge. Besides enjoying a large practice Dr. Holman has taken a prominent part in public affairs—as a justice of the peace and one of the pioneers in the establishment of the Reigate and Redhill Cottage Hospital. He is also, and has been for some years past, hon. treasurer of the Royal Medical Benevolent College, Epsom, an institution in which he has always taken the deepest interest, and for some years was the hon. treasurer of the British Medical Association. Dr. Holman succeeded two eminent country doctors—DRS. Thomas and Peter Martin—who in their day were regarded with no small degree of respect among their wide circle of patients—a respect which has been bestowed on their successor, towards whom all classes united in expressing their esteem on his relinquishing practice at Reigate. There was a large and distinguished company at the presentation. The Vicar of Reigate made the presentation in a very effective speech. Those, he said, who had known Dr. Holman in time of suffering would not readily forget his cheerful, reassuring voice by the sick bed, and his deep sympathy when skill and resource seemed to be of no avail. He would carry with him in his retirement a consciousness of duty done and of firm friendships formed. Dr. Holman, in acknowledging the gifts, said it had been his aim not only to be the doctor of the patient, but to be his friend. He had never believed in the simple application of drugs for the cure of disease, unless the medical man who was applying

Digitized by Google

those drugs was as deeply interested in the case as the patient who was suffering from the disease. He was thankful to say that during his professional career in Reigate he had enjoyed the affectionate confidence of his patients. In honouring him that day they were encouraging many members of an honourable profession.

THE BETHNAL GREEN AREA.

IT is satisfactory to know that the wretched quarter, lying immediately behind Shoreditch Church, called "the Bethnal-green area" is condemned, and will shortly be pulled down. Many of the cottages are already abandoned, but the majority of the inhabitants are still there, and the population is numerous. This being the case, we see no reason why the sanitary condition of this locality should be allowed to go from bad to worse. It is so bad that a scheme for the demolition of the quarter has been sanctioned. This, we should have thought, is a strong reason for keeping a very close watch over the district. The contrary appears to be the practice. On the pretext that the property is to be pulled down no repairs whatever are effected. We recently visited a small cottage where we found the pan of the closet broken. A wall which protected the row of small back yards had been demolished, and small boys amused themselves by flinging stones. One of these missiles had struck and broken the pan of the closet. On the other hand, the water waste preventer was deranged in such a manner that the water flowed incessantly, and, entering the broken pan, would soon flood the yard. To prevent the water reaching the closet the inhabitants opened the yard tap which was near a gully and drain. Thus in this cottage the water is running day and night; and, in spite of this great waste of water, the closet is in a filthy and most insanitary condition. A few shillings would probably suffice to effect the necessary repairs. The sanitary inspector has seen the place, the landlord has been communicated with, and yet nothing has been done. Nor is this the only case of such neglect in the locality, and this incident opens out an important question. Not merely a few weeks, but often several years, elapse between the time when a district is condemned or is about to be condemned and the time when it is actually demolished. During the whole of this interval no care is taken of the property, and even the most urgent defects or breakages are not repaired. Thus the danger to public health due to the existence of such quarters is increased for the time being by more than normal negligence.

THE LONDON WATER-SUPPLY INQUIRY.

THE inquiry into London's water-supply is progressing rapidly, and already much important and interesting evidence has been given. The engineers of the New River Company and the East London Company have been heard, and their joint evidence would appear to indicate that there is no reason to fear that the supply of water to London will become inadequate for some time yet. In 1891 the average daily supply of the New River Company was 33,028,000 gallons. Of these, 22,500,000 gallons came from the Lea, and the remainder from Chadwell springs and wells. The largest number of gallons supplied on a single day was 42,000,000, in January, 1891. The question of storing the water coming down the Lea in winter months was possible, and had been considered, although there was no scheme in hand for it. The engine superintendent of the New River Company, who has charge of the filtration of the water, said there was no possibility of communication between the filtered water and the drains below. The filter beds were periodically cleaned, and every care was taken to properly filter the water. The engineer of the East London Company felt certain that the water supplied by his company was improving. In the company's supply of 40,000,000 gallons a day they would take 20,000,000 gallons from the Lea, 10,000,000 from the Thames, and 6,000,000 from the wells, and they would get the remainder from storage. They could store 910,000,000 gallons. The water from the gravel springs at Hanworth, from which they could get 2,000,000 gallons, had turned out satisfactorily on analysis. Between the two companies it was proposed to draw something like 44,000,000 gallons a day from the chalk wells more than at present. There was a huge volume of water passing into the Thames from that locality, and it was stated that the fact of their drawing this amount per day would not be much felt—if felt at all—by those living in the locality. Their water would come from below the clay, so that the surface water above the level of the clay would not be touched. Further evidence, of course, will be heard on the question of the quality of the supplies, and it is to be hoped that the grave complaints that have been recently made about the condition of the water supplied by certain companies will come on for consideration. Some explanation may be looked for also of the fact that, during periods of drought a few years ago, one of the companies was compelled to limit the supply by cutting off the water at various times through the day. The increase that has taken place during the last twenty years in the number of houses in the districts supplied by the companies is not the least formidable fact which confronts the Commission, and only that future scheme can be accepted which shall provide for the abundant supply of pure water in times normal and abnormal.

OBSTETRICS AND GYNÆCOLOGY IN MOSCOW.

THE report of the lying-in-department of the Golitsinski Hospital in Moscow for 1891, by Dr. Inoieffs, has just been published, and in addition to its statistics contains several interesting papers. The total number of labours conducted in the department during the year was 713. Very nearly equal numbers of these were concluded during each of the four quarters of the day, the slight difference existing being in favour of the evening quarter—namely, from 6 P.M. to midnight. Detailed tabular observations are given of the 17 cases of twins and of the 24 cases of contracted pelvis, that is to say, where the external conjugate diameter was below 18 centimetres. There were 4 fatal cases—1 from croupous pneumonia, 2 from anæmia, and 1 from septic endometritis and parametritis. The antiseptic employed was corrosive sublimate. The use of the forceps was required in 15 cases, laceration of the perineum occurred in 14 cases, and rupture in 17. There were 7 cases of craniotomy, and one of evisceration. With regard to the puerperal period, there was no fever—i.e., temperature above 38° C.—or other complication in 599, or 84·1 per cent., of the cases. There were only 8 cases of true puerperal diseases—i.e., 2 of colpitis with endometritis, 4 of endometritis, one (fatal) of septic parametritis with endometritis, and one of mania. In the 8285 cases attended in the department since 1868 there have been 309 cases of true puerperal diseases and 64 deaths, 20 of which are attributed to non-puerperal affections. In all this number the employment of the forceps was required only in 189 cases, craniotomy was performed 33 times, and evisceration once only. There is no mention of the Cæsarean operation. Amongst the reports of the gynæcological sections there is one dealing with electrical treatment by Dr. Dyski, a tabular view of twenty-eight cases being given. The best result was obtained in parametritis, a lesser degree of success being secured in oöphoritis, and still less in salpingitis. With regard to fibromata, some degree of subjective improvement was

Digitized by Google

always obtained, but the tumour did not in any case appear to become reduced in size. This agrees with the experience of most other Russian writers on the subject—Massen, Himmelfarb, and Kholmogoroff, — though Neêloff, who reported twenty cases to the Kieff Obstetrical Society in 1890, had succeeded in reducing the tumour in seven instances to some small extent. Dr. Dyski calls attention to two cases of gonorrhœal endometritis which had been treated unsuccessfully by various ordinary methods, and which only yielded to repeated electrical applications, the anode being introduced into the cavity of the uterus. In one case the discharge so nearly ceased that the patient considered herself cured, and did not return after eighteen sittings; the other, which was complicated with salpingitis and perisalpingitis, was quite cured after twelve applications of the induced and six of the constant current. Dr. Dyski remarks that the antiseptic properties of the anode of a galvanic current render it a peculiarly suitable agent in obstinate gonorrhœa of the internal genital organs in the female. It is of course advisable in all gynæcological cases where electricity is employed not to depend upon it entirely, but to make use of other local and general treatment simultaneously with it. In several of the cases described in the table the induced current was used for the earlier sittings and the constant current in the later ones.

THE NOISE OF BANDS OF MUSIC.

MR. MOSSE, treasurer of St. George's Hospital, writes to a contemporary to ask those societies which assemble in the parks, and are accompanied by bands of music, to be good enough to direct the bands to cease playing while passing near the hospital. The request is reasonable, and will doubtless be regarded. The amount of suffering occasioned in London by the noise of the streets will never be known. All who have any influence will do great good by reducing it in every way. It must be allowed that the methods of many good associations are clamorous. Take, for example, the noise and disturbance of the streets on a Sunday caused by a "lodge" undertaking to make a collection for a blind asylum or a hospital. Surely the highly organised lodges can do their benevolent work without the sound of trumpet and the beat of drum.

DIRT AND DISCOMFORT AT CORONERS' INQUESTS.

THE report of an inquest held at Battersea a few days ago reminds us of the delays and inconveniences connected with such occasions which, not always with due reason, absorb the time and patience of medical men. In the case referred to the body of the deceased had not been cleansed prior to post-mortem examination either by relatives or by any official, the mortuary being without an attendant. Consequently the discharge of this preliminary duty fell to the share of the medical witness employed upon the case. The matter was mentioned in court, and the jury very rightly maintained that bodies in future should be cleansed and prepared prior to examination. They also recommended that a mortuary keeper should be provided by the local vestry. This decision will commend itself as an expression of moderation and good sense. It is obvious that no mortuary room can be efficiently managed without a regularly appointed attendant, and the cleansing of the dead, if allowed to be neglected by friends or neighbours, should certainly be carried out by such an official rather than by the practitioner. There are certain other defects in the management of these official investigations which invite attention. Take, for example, one which almost ensures uncleanliness in the operator—the want of a supply of hot water. At the present day an examination will be completed in all its impurity, and the practitioner finds himself confronted by the further impossible task of trying to clean his hands and instruments with cold water, and perhaps a little crude carbolic acid. Another similar omission, if not of quite such absolute and primary importance, has much to do with the reasonable demands of civilised usage. This consists in the frequent absence or disuse in mortuaries of warming apparatus. For want of this we have become familiar with the painful spectacle of medical men shivering in the cold of a hard winter whilst performing duties certainly appertaining to their profession, but none the less of a decidedly unpleasant nature. Why should they be condemned to this penance? The cost of an occasional fire would suffice to do away with it; and this much at least should, we consider, be provided by the authorities. The above suggestions are not made merely in the interests of the medical profession. In the defects which they are intended to amend, and their inconvenient, or possibly even injurious, consequences, the public is also concerned. Let it therefore, like the Battersea jury, bring light to bear on some evident official errors, and seek to secure the correction of these by every lawful means.

THE HEALTH OF SOUTHEND.

WE referred incidentally on a recent occasion to a report on the system of sewers in Southend which was in course of preparation. When publicity was first given to the sanitary state of that town, Dr. Thresh advised that an expert in engineering should be called in, which advice was adopted. Mr. Mansergh advises that the sewers should be divided into high and low level systems, the latter to include all sewers which are tide-locked at high water—an arrangement, too, that will involve pumping of sewage; he further recommends enlargement of a sewer, improvement of gradient where the sewers are not self-cleansing, some prospective works in providing new overflow sewers, increased sewer ventilation and flushing, the stoppage of leakage, and the provision of increased outfall arrangements. The recommendations seem to cover a wide scope; but it still remains to be seen what is proposed as to the outfalls, as to which Mr. Mansergh reserves his report. We trust the sanitary authority will face the whole of the difficulties which are dealt with in the report which they have already received, and also the perhaps larger difficulty that may be involved in the matter of outfalls, which Mr. Mansergh promises to deal with "at a subsequent date."

DIPTERA AS PARASITES.

IN the *Journal of the American Medical Association* for April 9th, 1892, is an account of a human parasite, which, so far as we are aware, is unknown in this country. The particular case to which the article relates is recorded in a paper known as *Insect Life*. It records the case of a lady of St. Louis who suffered from the hominivorous habits of the "screw-worm." The attack commenced with nasal irritation, causing sneezing paroxysms of great violence. A diagnosis and treatment for influenza met with failure. The patient grew worse on the second and third days, having intense pain between the eyes, with considerable swelling of the face, nares, eyes, and pharynx. On the fourth day two or three white worms were expelled from the nose by sneezing, which led to a local examination, and hence a new diagnosis. Many white larvæ were seen attached to the nasal mucous membrane as far as its swollen condition permitted it to be seen. By instrumental means about thirty larvæ were extracted. Chloroform spraying and solutions of carbolic acid were not effectual in making the parasites loosen their hold. Indeed, every attempt to dislodge them caused them to retract and bury themselves more deeply in

Digitized by Google

the tumified and bleeding tissues. During the next three days instrumental means were continued by the medical men in attendance, and over two hundred larvæ were removed and put in alcohol. Some of them were taken from the posterior surface of the tonsils and nares by the use of indirect illumination and curved forceps. On the eighth day no more larvæ could be found, and relief began to be experienced; the inflammatory condition subsided and the structures infested by the larvæ gradually recovered tone and normal function without any permanent injury to any part. But meanwhile, during the acute period of her suffering, the patient developed a suicidal mania. She implored her attendants to allow her to end her life, and even argued with her physician upon the advantage to herself and family if her life could be ended. This suicidal tendency has been observed before in patients suffering from an attack of the "screw-worm," and all such patients require to be constantly watched during the acute period. The larvæ which were removed were nearly all fully grown, and would probably have come away spontaneously in another day. The method and time of lodgment of the ova could not be ascertained, beyond an indistinct recollection on the part of the patient of some moderate nasal disturbance after sleeping near an open window; there was no history of catarrh or ozæna. Cases of this kind of parasitic trouble, the article goes on to say, have been not uncommon at the St. Louis City Hospital. In the summer of 1888 there were five or six cases, four in 1889, three in 1890, and one or more in 1891. The assistant superintendent of the hospital is quoted as saying that "one of the cases in 1890 died from the exhaustion of the attack, and one died from an intercurrent disease while affected with a worm." Others recovered, but with greater or less mutilation. Not a few of these cases were in persons who were known to have slept in the open air, probably receiving the infecting ova while thus exposed. The cases generally occur in the more southerly localities, but it is by no means certain that all these parasitic invasions have the same genus of blowfly as their originator.

BOARDS OF GUARDIANS AND THE LATE INFLUENZA EPIDEMIC.

WE have observed with satisfaction the tendency exhibited by boards of guardians to adequately remunerate their medical officers in the discharge of their arduous duties at a time of great pressure, we may almost say panic, entailed by the influenza epidemic. Unfortunately the Risbridge Board (Suffolk) cannot be included amongst these liberal authorities. The medical officer for the second district of the union (Mr. Edward A. Piggott), having applied under Article 72 of the General Consolidated Orders for "a reasonable compensation on account of extraordinary services," received the following laconic reply to his application—viz., "The guardians, having considered your application, resolved that it be not further entertained." It is generally conceded by most right-thinking persons that "the labourer is worthy of his hire." The guardians of the Risbridge Union evidently think otherwise.

LEAD POISONING FROM WATER.

A REPORT reaches us of a fatal case of acute "plumbism" of two days' duration, caused by drinking the water supplied by the Bradford Corporation to the neighbouring district of North Brierly. According to the evidence at the coroner's inquest, Mr. Dearden stated he was called to see the deceased, and found the skin cold and damp, with retraction of the abdominal muscles; the patient suffered from vomiting and collapse, and a most pronounced blue line was found on the gums. Mr. Dearden also stated that during the last twelve months he had attended about thirty cases of plumbism, none of which, however, had proved fatal. During the last three years he had seen on an average one fresh case of lead poisoning a week. For some time the deceased, during last summer, had a strong objection to the water supplied by the local board, and this induced him to carry water from a spring in his garden for use in his workshop. A severe and isolated case of plumbism like this, especially when there was a history of an independent water-supply, might be passed over as due to some special contamination; but the evidence of Mr. Dearden as to the existence of plumbism, so widely distributed amongst the population, raises strong suspicion that the contamination arises from the water supplied by the Local Board. Our readers will remember that in the case of the extensive outbreak of lead poisoning at Sheffield, which was the subject of a most searching inquiry, the earliest cases which came under observation were scattered among the poorer inhabitants, and that many medical men in the town were sceptical as to the real condition of affairs, till the poisoning assumed quite an epidemic character. As we have frequently pointed out, the action of certain waters on lead pipes is very insidious, and the first to be affected are those who are peculiarly susceptible to its action. Many circumstances, such as using the water first drawn in the morning, or extra pressure from the waterworks washing off the deposited carbonate of lead from the house pipes, may intensify the action of the poison by concentrating it. Whatever the cause may be in the case of the water supplied in this instance, the Bradford Corporation should at once undertake a searching investigation to ascertain whether the defect is local or general. They should carefully study the history of the Sheffield outbreak; for if with this warning they await events till "plumbism" becomes epidemic, they will incur grave responsibility.

THE PRESIDENT OF THE LOCAL GOVERNMENT BOARD.

WE much regret to hear that Mr. Ritchie is again indisposed. He is unfortunately suffering from a recurrence of the ischiatic abscess with which he was troubled a year ago. This has been relieved by operation, but it will of course involve his absence from public duties for a brief period.

AN "ERROR OF JUDGMENT" BY A GERMAN PHYSICIAN.

WE may without presumption congratulate the profession that its members are not often guilty of such a deplorable "error of judgment" as that which resulted in the recent imprisonment of a German physician. In this case the director of an establishment for the treatment of nervous disease was convicted of having assaulted, beaten, and whipped a hysterical lady patient under his care. The sentence of three months' imprisonment was, in our opinion, a remarkably lenient one. We must admit that in all probability the patience of the medical superintendent was often tried. No class of patients can be more aggravating when they choose than those who, while possessing their ordinary intellectual faculties, are either so weak or so perverse in will as to be practically the mere automata of disordered impulses. It is to be remembered, nevertheless, that the violence of blind force provides no remedy. Chastisement even in the case of children of itself is valueless unless it be guided by rule, unless it be used, we might say, medicinally. It has, like any drug, its appropriate aim and purpose, its proper action, its dose limited by known effects, and its hurtful excess. But in the case of adults physical correction is, of course, inadmissible where disease is concerned. It should be

Digitized by Google

remembered also that even with apparently pure hysteria there may coexist the germ of true lunacy, and this must be allowed for whenever restrictive means are thought of. The German physician who has in the case recorded, so inexcusably erred in his treatment will, we are assured, not find imitators in our own country.

THE GOOD SAMARITAN.

SPEAKING in a light and happy vein at the King's College Hospital Festival Dinner, before an audience composed largely of lawyers, although many eminent divines and doctors were present, the Attorney-General (Sir Richard Webster) playfully claimed to have found by a process of exclusion that the Good Samaritan must have been a lawyer. He gave his reasons for not assigning the distinction to various learned professions, and finally reached the conclusion that he must have been either a lawyer or a doctor, and then thought he had proved his point, because "no doctor would have poured oil and wine into an open wound." It would be treating Sir Richard Webster too harshly to consider this in the light of anything but an after-dinner joke, otherwise a very cursory reference to the history of the past would show that modern antiseptic treatment has only been reached by slow and painful stages, and that in the early days of surgery almost anything, solid or liquid, might have been employed in the treatment of wounds. We need go no further back than the *Arcana Fairfaxiana* of the seventeenth century to realise this somewhat humiliating fact; so that, in spite of Sir Richard Webster, those of a speculative turn of mind may still feel free to maintain that in the original parable the Good Samaritan was, as in the present day he so often is, a medical man.

HOUSING OF THE POOR IN AUSTRIA.

THE Austro-Hungarian Legislature has recently made an effort to deal with the unwholesome dwellings that abound in the poorer districts of the great towns. A new law has been enacted, and it bears the date of Feb. 9th, 1892. It is too soon, therefore, to say whether this measure will effect much good; but the prospect, it must be admitted, is not very hopeful. The law takes no action in the sense of demolishing unwholesome dwellings or of constructing better houses, it only encourages private initiative. This encouragement is given by exempting from taxation during twenty-four years workmen's dwellings built under certain conditions. First, it is stipulated that if the State withholds its right to tax, the local authority must act in a similar manner; thus the houses in question will be exempt at once from Imperial taxation and from local rates. The houses that are to enjoy such immunity must be built by the Communes or local authorities or by societies recognised as of public utility, or by establishments instituted in favour of the working-classes, by coöperative workmen societies, or by employers for their workmen. The law then goes on to enact that the houses built, to be exempt from taxation, must not have any dwelling-room below the level of the soil. Also tenements consisting of one single room must possess at least fifteen square metres of habitable surface, and not more than thirty square metres. If the tenement consists of several rooms these must not measure less than forty square metres, and not more than seventy-five square metres. Thus the law deals only with small tenements, but measures are taken to prevent these tenements being too small. Again, the law is to be applied only to cheap tenements, and a maximum rent is established. The rent is estimated per square metre of habitable surface, and is fixed at 1·75 florins per annum at Vienna. In all other towns which have more than 10,000 inhabitants the rent that may be charged shall not exceed 1·15 florins per annum per habitable square metre, and in all other places eighty kreutzers, or 0·80 of a florin per square metre. The silver or paper florin is worth 1*s.* 8*d.*, but the florin in gold is worth 2*s.* Presumably the law will apply to the usual currency—namely, the paper and silver florin. Should a higher rent be charged than that laid down by the law, a fine equal to ten times the amount of the overcharge will be imposed. The produce of such fines will be paid into the local poor box. Finally, and as if to hasten the work of rehousing the poor, a clause states that the benefits of this law shall only be accorded to such houses as are built within the next ten years. In other words, the Austrian Government offers twenty-four years' immunity from taxation to those who will within the next ten years build better and cheaper houses for the poor. This is satisfactory so far as it goes, but our experience in England teaches us that more than this will be necessary. The new law may do some good, yet it certainly will not solve the problem.

SLANDER AGAINST MEDICAL MEN.

THE case of Ward *v.* Hatfield is an instance of the facility with which the obvious and common words of a medical man may be misconstrued and turned into a ground of legal action against him. This was a case tried before Mr. Justice Hawkins, in which a nurse attending an obstetric case followed by purulent discharge, and proposing to attend another obstetric patient of the same practitioner, was advised by him to wash her hands carefully, as the discharge might be catching. The husband regarded this as equivalent to saying that his wife was suffering from venereal disease. An explanation was given and seemed to be accepted. But afterwards an action for slander was tried. It completely broke down. The witnesses for the defence were not even called. The judge stopped the case and directed a verdict for the defendant, with costs. The case is an instance of another fact—the advantage of being a member of the Defence Union. The plaintiff, in a letter to us, mentions how great was the comfort to him of having this effective organisation at his back to give him help and consideration.

THEMIS AND HYGIEIA.

HOW is it that the Goddess of Justice is so seldom "at home" to the Goddess of Health? If there is an abode in the community where hygienic science is systematically ignored, it is wellnigh invariably a court of law. The fact comes periodically before us in the shape of indignant protests on the part of judge and counsel condemned to pass their professional lives in an atmosphere which, compared with that wherein the social pariah they have mostly to deal with lives and moves, is as the "Inferno" to the "Paradiso" of Dante. The latest "bitter cry" from forensic quarters now reaches us from Edinburgh, where the Lord Justice Clerk (Lord Kingsburgh) recommends the court over which he so worthily presides as the fittest of all places for object lessons in bad ventilation. Dr. C. Hunter Stewart, in the course of some most interesting researches into the air of public buildings, had been combating the view that carbonic acid is the baneful element in the atmosphere of these resorts, and had shown that it was the organic matter exhaled from the skins and the clothes of their inmates that constituted the real source of mischief. Not the products of respiration, but "animal steam" was the cause of the pathological results arising from occupancy of those buildings, and he quoted in point the German army doctor who had all the soldiers of a particular barrack compulsorily bathed, with the effect of inducing a very marked improvement on the ventilation of the tenement. Upon this Lord Kingsburgh invited Dr. Stewart to carry his researches into the Edinburgh law

Digitized by Google

courts, where "he would find a much richer field in the way of organic matter and of everything else that was bad than any place he had yet tested." His lordship added—what is not more true of Edinburgh than of Dublin or the metropolis itself—that the "great unwashed" frequented the law courts more than any other class of the community. "It was the only theatre they had for which they had to pay nothing, and it was at the time when judges and counsel were under the severest mental strain that the courts were crowded with human beings, most of whom would be the better of having the German doctor's discipline enforced." Lord McLaren, impressed with the truth of this remark, "concurred with his learned brother," and added "that, since the courts must be open to the public, and only a limited number could be admitted, they should insist on no one coming in without being decently attired." Whether this is "the true solution of the matter," which Lord McLaren took it to be, we are doubtful; but it would be well if Themis took occasionally a leaf out of the book of Hygieia, and treated her in more sisterly fashion than she has sometimes been known to do.

THE PREVALENCE OF SMALL-POX.

SMALL-POX still continues to spread. In the metropolis the number of new cases per diem exceeds any statistics recorded for some years. At Halifax fresh cases are arising, and the disease has appeared in several neighbouring places, such as Brighouse, Brookfoot, Rastrick, &c. The result is some considerable activity as regards proposals to erect hospitals either for districts singly or by twenty or more districts jointly. It is to be hoped that, with advancing summer, such arrangements, if made at once, will be really of a temporary nature; for few things have done so much to hinder the provision of adequate means of isolation for infectious diseases generally as the erection of semi-permanent hospitals which, at the moment, were styled "temporary." At Yarmouth considerable measures of precaution have been adopted. Twenty-seven inspectors were appointed to make a house-to-house visitation of the town, and to secure the vaccination of the unvaccinated and the revaccination of those running risk of infection. The infection hospital has been used for isolation purposes, and Dr. Bately reports that of the forty-nine cases that have occurred the greater number had been removed to the hospital on the Denes, and were now convalescing or convalescent.

NERVOUS SYMPTOMS AND SEQUELÆ OF INFLUENZA.

DR. C. K. MILLS of Philadelphia has published an exhaustive paper on this prolific subject, reprinted from the Transactions of the Philadelphia County Medical Society. The difficult question of discussing the nervous and mental phenomena of influenza he treats by dividing such phenomena into three classes:—(1) Symptoms and conditions which, although manifested in non-nervous organs, are directly traceable to a nervous origin; (2) affections which all would recognise as properly referable to the nervous system; and (3) affections occurring in nervous tissues and organs, although not constituting strictly nervous diseases. As regards the first class, he thinks that many of the most prominent pulmonary, cardiac, and vascular affections of influenza can best be explained on theories of nervous origin, and that, for example, the pneumonia of influenza is often due to vaso-motor paralysis. But to the neurologist the most interesting and important diseases developed either during or subsequently to an attack of influenza are those in which there are organic changes in different parts of the nervous system. Among such diseases are various forms of neuritis, including multiple neuritis, isolated neuritis, neuritis of cranial nerves, &c. The conditions in one class of cases—viz., articular and other pains with swelling—closely resemble those found in beri-beri. Cases of myelitis are also described as occurring, and anterior poliomyelitis and its analogue, bulbar paralysis, have also been described. Then there is quite an array of cerebral affections, including meningitis, hæmorrhage, and local effusions. A great many affections are ascribed to influenza, probably in numerous instances rightly so. But there is no doubt that a great tendency has to be guarded against—namely, that which ascribes all kinds of peculiar symptoms to influenza, or which makes any common condition occurring at a time when influenza is prevalent, dependent upon this disease. It is too often lost sight of that the initial malaise in such a condition, for example, as anterior poliomyelitis is put down as an attack of influenza, when under ordinary circumstances, and if influenza were not prevalent, no such explanation would be sought for. That we had amongst us recently an epidemic condition of a most serious kind no one who takes the trouble even to glance at statistics will deny; but we have little doubt that influenza has been invoked as an explanation on numerous occasions when it could more reasonably have been left with its already too great burden. Dr. Mills, in his discussion of the subject, more particularly from the neurologist's point of view, has not, we venture to think, erred on the side of excluding any of the possible manifestations of nervous disorder following or accompanying influenza.

NOTIFICATION AND THE MEDICAL PRACTITIONER.

WE receive from time to time inquiries as to the relations which should exist between medical officers of health and other medical practitioners in the matter of certificates under the Act for the Notification of Infectious Diseases; and we would therefore draw attention to a thoughtful paper on the subject in this month's issue of the *Practitioner* by Dr. Edward T. Wilson of Cheltenham. The paper embodies advice which is in most respects much the same as that which we have given to correspondents from time to time, and it has the advantage of quoting in detail a number of letters which the Local Government Board have addressed to sanitary authorities, health officers, or medical practitioners who have made inquiry on certain definite points. The paper will be useful to many practitioners who are vexed with doubts as to the altered relations which have been brought about by the Act between themselves and medical officers of health.

EFFECTS OF MEDICATED INHALATIONS.

DR. A. IRSAI of Buda-Pesth has made some instructive laboratory observations on the effects of the inhalation of various substances on the lungs and air passages. Almost immediately after a few inhalations of air impregnated with oleum terebinthinæ the lungs became pale, but regained their ordinary appearance on the readmission of pure air; a second administration of turpentine vapour was followed by the same appearances as the first. The cause of the pallor was doubtless a spasmodic contraction of the pulmonary vessels—probably due mainly to peripheral action. When oleum juniperi or oleum pini sylvestris was employed, results of a similar kind, but less in degree, were obtained. Oleum pini sylvestris, however, is a more powerful vaso-motor constrictor than oleum terebinthinæ. With eucalyptus, oleum anisi, oleum menthæ, and menthol scarcely any change was produced in the colour of the lungs. With oleum thymi and thymol three or four inspirations were followed by a distinct reddening, which increased as they were continued. Creasote and, in a still

Digitized by Google

greater degree, guaiacol produced redness, there being rapid relaxation of the vessels and great hyperæmia of the lungs. From these observations Dr. Irsai concludes that in acute catarrhal affections with swelling, hyperæmia, and profuse secretion, substances should be selected for inhalation which produce anæmia, and that in chronic torpid conditions, or in phthisis where the supply of blood and the nutrition of portions of the lung are defective, substances which induce hyperæmia should be used. Of course it is needful to exercise due vigilance in employing creasote or guaiacol in cases where there is any tendency to hæmorrhage.

NOTIFICATION OF ENTERIC FEVER.

OWING to the system of notification of infectious diseases prompt action has been taken by Mr. Williams, the medical officer of health of Plymouth, to stay the progress of an outbreak of enteric fever which, unknown to the dairyman himself, was being distributed through the agency of his milk. When the matter was investigated strong suspicion was found to attach to the water-supply of the dairy farm whence the milk was derived, although at the time of the inquiry the water was found to be pure in so far as chemical tests were concerned. It was also ascertained later on that just before the occurrence in question a child had died at the farm of enteric fever, and at the date of the inquiry a second person was found to be suffering from the same disease. The precautions taken, including a cessation in the sale of this milk, were followed by an absence of further attacks.

PREVENTIVE DENTISTRY.

THERE are two prophecies current concerning the future of dentistry, writes Mr. Wm. Rushton in the current number of the *British Journal of Dental Science*. One—the optimistic—predicts that in time preventive dentistry (as contrasted with conservative dentistry of to-day) will successfully oppose the many adversaries which now attack the teeth; the other prophecy—the pessimistic—maintains that man will become a recruit to the ranks of the order Edentata, and that future generations will not only be toothless, but hairless and spectacled. In other words, it is held that the dentistry of the future will be the adaptation of mechanical appliances to edentulous mouths. Mr. Rushton, however, thinks that the mean between these two extremes, comes nearest the truth, that the preventive treatment of the future will do much to arrest further deterioration of tooth tissue, but that teeth will never, in highly civilised communities, be brought back to the normal state as found in the skulls of our early forefathers. Much good, he is assured, may be done by more attention being given to the general health, by the teaching of cooking especially amongst the poorer classes, and by the aid of the dental surgeon, whose services are now not alone the privilege of the wealthy, but are fast becoming available for all.

PROPOSED AMENDMENTS OF THE FOOD AND DRUGS ACT.

SOME important changes in the Sale of Food and Drugs Act are embodied in a Bill recently prepared and brought in by Dr. Cameron, Mr. Channing, Mr. Provand, Dr. Farquharson, and Mr. Thomas Dickson. It enacts that the provisions of the Act of 1875 shall apply to and include every wholesale trader or manufacturer of any article of food or drug who shall sell to the prejudice of the purchaser any article which is not of the nature, substance, and quality of the article demanded by such purchaser. The twenty-fifth section shall be amended by the deletion of the word "written" before the words "warranty to that effect"; and every wholesale trader or other person who shall sell to any person any article of food or drug with intent that the same may be resold by retail in the state in which it is purchased from him shall, unless he has in writing informed the purchaser to the contrary, be deemed to have given a warranty to the person purchasing from him that such article is of the nature, substance, and quality demanded by such purchaser. A new section as to margarine provides that it shall be a good defence to prove that the sale was made in conformity with the regulations of the Margarine Act, 1887. With regard to the provisions as to the mixtures of chicory and coffee, the Bill states, it shall be a good defence to prove that, first, where the admixture of chicory does not exceed 50 per cent., that the seller delivered with or on such a mixture a notice by a label, distinctly and legibly written or printed, bearing the words, "This is sold as a mixture of coffee and chicory"; secondly, where the admixture of chicory does not exceed 75 per cent., the words, "This is sold as a mixture of chicory and coffee"; and, thirdly, where the admixture of chicory exceeds 75 per cent., that the seller delivered with or on such a mixture a notice by a label stating the proportion of chicory contained in such mixture.

THE METROPOLITAN PROVIDENT MEDICAL ASSOCIATION.

WHATEVER the merits of provident medical associations, there seems no justification for the indiscriminate offer of their cheap terms to all and sundry persons, without distinction of class and without conditions as to means, income, &c. The instance before us is that of a bill delivered at every house in a road of good houses, including those medical men. There are eight plain reasons given why "you" should join the Hackney Provident Dispensary, one of which is "because whole families may join and insure against the risk of heavy bills which it is often difficult to pay." The wholesale distribution of such literature among the patients of other medical men is an offence to the profession and a demoralising influence to those to whom it is sent. Such a thing as a wage-limit is not suggested, and all and sundry are taught that the very cream of advice and medicine is to be had for sixpence a month.

THE PUNISHMENT OF HABITUAL DRUNKARDS.

The Times gives the following as the departmental committee appointed by the Home Secretary to inquire into the best mode of dealing with habitual drunkards:—Mr. J. L. Wharton, M.P., chairman; Sir Guyer Hunter, M.P.; Mr. E. Leigh Pemberton, Assistant Under-Secretary of the Home Department; Mr. C. S. Murdoch, head of the Criminal Department, Home Office; and Dr. Nicolson, Superintendent of Broadmoor Criminal Lunatic Asylum. In his reference to the committee Mr. Matthews says: "Great difference of opinion has arisen as to what kind and degree of punishment for offences committed by habitual drunkards would be the most effectual, both as a deterrent and with a view to the reformation of such offenders. It appears to me that advantage would result from an inquiry being made into the subject." It will be seen that this inquiry refers only to punishment of habitual drunkards who commit offences. The first meeting of this Committee takes place to-day (Friday), 20th inst., at twelve o'clock.

FOREIGN UNIVERSITY INTELLIGENCE.

Gratz.—Dr. Elschnigg has been officially recognised as *privat docent* in Ophthalmology.

Innsbrück.—Dr. Jarisch has been promoted to the professorship in ordinary of Dermatology and Syphilis.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—

Digitized by Google

Dr. Christian Wilhelm Ludwig Abel, recently retired from the post of medical officer in command of the Second Prussian Army Corps. He was sixty-six years of age. He served with distinction in the Danish, Austrian, and French wars. He had written a great deal on professional and military medical subjects, and was for a time one of the editors of the *Preussische Militärärztliche Zeitung*.—Dr. E. Mühsam, a well known and much respected Berlin practitioner.

HER ROYAL HIGHNESS PRINCESS CHRISTIAN will write a paper on the work and organisation of the Royal British Nurses' Association, which is to be read in the Women's Section of the Exhibition at Chicago in 1893.

THE Islington vestry have recommended, with regard to the permanent appointment of a medical officer of health for that district, that the salary should commence at £600 a year, and be raised by yearly instalments of £25 to £800.

THE LANCET
Special Analytical Commission
ON
MINERAL WATERS, TEMPERANCE BEVERAGES, &c.

II.—KOP'S ALE.

IN THE LANCET of August 8th, 1891, we published the report of our Special Analytical Commission on an interesting natural mineral water—Johannis. In continuation of the series we now select for investigation a temperance beverage.

Temperance advocates have not been considered in the matter of beverages as they deserve. While they deny to themselves, from various causes, the beverages which appeal to most palates, and which are objectionable to them on the score of containing alcohol, few are available that can be regarded as really good substitutes for beer or other alcoholic liquors. Yet the temperance cause is growing apace, and its ranks are steadily increasing year by year, and to abstainers the urgent question arises, "What shall we drink?" It must be disappointing to the advocates of the cause that the question does not appear to find a satisfactory answer. As a glance down the records of our analytical work during the past few years will show, we have not omitted to give attention to the matter of beverages, and especially to those which claim to be palatable though non-alcoholic, or at least non-intoxicating; but in few instances have we met with a truly satisfactory article, or, at any rate, one which would remain for a time without generating alcohol or deteriorating in some other way. It is really a very difficult thing to prepare a beverage perfectly free from alcohol. Some drinks regarded as non-alcoholic, and for that reason consumed by teetotallers, contain alcohol sometimes equal in amount to ordinary brewers' ale. Thus ginger-beer may easily contain from 1 to 3 per cent., since it is mainly prepared with sugar and yeast. Artificially aerated drinks, of course, such as soda-water, lemonade, and ginger-ale, contain no alcohol; but there is lacking about these an ill-defined "something" which nevertheless contributes largely to fermented liquors that distinctive character and taste for which they are held in esteem. The complicated process of fermentation, quite apart from the alcohol produced or the saccharine substances present, does unquestionably influence in a higher degree than can at present be explained by science, the flavour and character of the final product. If the composition of beer, for example, be imitated by making simply a decoction of hops and adding malt wort or extract to the decoction, and afterwards impregnating with carbonic acid gas, the taste, when compared with the fermented liquor containing precisely the same ingredients, will be found wanting in tone, brightness, and vigour. That fermentation materially softens and tones the character of beverages is a fact which the promoter of the present subject of our inquiry has not lost sight of. The "ale," known as "Kop's" is now so largely consumed by a considerable section of the public, both teetotal and temperate, that we decided a short time since to submit the article to exhaustive examination, and we have now to place on record the results of the numerous analyses subsequently made. Our examination brought many facts to light, and as a consequence we were curious to know how so promising an article was prepared. Our commissioner visited Kop's brewery at Fulham, where everything was laid open to his inspection, and where not a single operation in the whole brewery was allowed to escape his notice, albeit there were many steps in the process of a secret nature. The brewery is a large imposing building covering some three acres of ground, another three acres being devoted to various outbuildings constructed for packing, case making, stabling, &c. The building contains almost exactly the same machinery and plant which are or should be incidental to an ordinary well-appointed brewery. There are the coppers in which the liquor is boiled, coolers, fermenting vats, storage vats, clarifiers, and so on. We may touch very briefly on the more important points in the manufacture before we consider the quality or nature of the final product, as is indicated by the analyses below. Water from two deep artesian wells outside is first pumped up to the top floor of the building into cisterns lined with enamel. The water is run off as required into huge jacketed boilers, where it is boiled with best cane sugar, hops, horehound, and a little ginger. The solution is then passed over a rapid condenser into the fermentation vats, where it is "yeasted" with ordinary brewers' yeast. Fermentation is soon set up and allowed to go on to a certain point, the process at the same time being kept under absolute control by carefully selecting the yeast and by regulating the temperature to a nicety. After being skimmed, the liquor is then run into closed vats, contained in the clarifying department on the same floor. Here, by means of air-pumps, it is put under pressure of a few atmospheres, which suffices to force it through a cylinder packed tightly with a specially prepared kind of cotton fibre. This effects a partial clarification of the liquor and removes all excess of yeast. The liquor then passes on to an ingenious filtering arrangement in which there are some two hundred sheets of ordinary filter paper, and between each sheet is a small metal plate provided with several grooves on the surface; so that the "beer" entering the top end of the filter runs down the first groove between the metal and paper, up the second, down the third, and so on until it reaches the next compartment. Although the beer has to pass, it is stated, through something like a mile and a half of filtering material, the cylinder is not more than three feet long. It is then stored in vats and slightly syruped. The now almost finished liquor next gravitates down to the aerating floor, where, with the best possible description of machinery and by various ingenious devices, the beer is aerated, bottled, and the bottles stoppered. Some sixty hands find constant employment in this department. The beer has but little chance of becoming contaminated with objectionable metals, as nothing but the cleanest copper and block-tin are used. Such is a brief account of the principal operations concerned in the production of Kop's ale. Turning now to the analysis and examination of the products, we may at the outset state that we secured not only samples of the liquor at every stage in the process, but also samples of all the materials used in its preparation. To begin with, our attention was given to the water used in the brewing process. It is obtained from an artesian well a few yards from the main building at a depth of 400 feet. The water is quite bright, has a cool, fresh taste, but possesses no smell. Submitted to analysis, the following results were obtained:—

Free or saline ammonia	0·025	grains per gallon.
Albuminoid ammonia	none	
Chlorine	2·23	"
Nitrogen in nitrates or nitrites	none	
Total solid matter	21·00	"
Temporary hardness ($CaCO_3$)	2·55	"
Permanent hardness ($CaSO_4$)	3·60	"
Total hardness	6·15	"

The water is remarkable for its purity and soft character. Of the total solid matter, which is less by eight grains than the Thames supplies, only 2·55 grains consist

Digitized by Google

of temporary hardness ($CaCO_3$) and 3·60 grains of permanent ($CaSO_4$) hardness, giving a total hardness equal to only 6·15 grains of lime or magnesium salts per gallon. No sign of organic matter was indicated by the albuminoid ammonia process or by the behaviour of the solids on ignition, or by microscopical examination; the chlorine is also normal—that is, not more than is commonly found in Thames supplies. The water is therefore not only of excellent quality for drinking purposes, but well adapted also for brewing operations. One other noteworthy feature, is the entire absence of nitrates, although the saline ammonia is rather high. We next submitted to analysis a sample of the liquor after fermentation, and the following are the results:—

Absolute alcohol	0·32	per cent. by weight
Equal to absolute alcohol	0·40	„ „ „ volume
Equal to proof spirit	0·70	„ „
Total solid matter	0·134	„ „
Mineral matter	0·029	„ „

The liquor was pleasantly bitter to the taste, turbid, and contained an abundance of healthy yeast cells, traces of sugar, the essential principles of hop, besides certain ill-defined but important products of fermentation. Soluble and insoluble phosphates were found in the mineral matter.

The next sample analysed was taken after the filtering operation. Here, as will be seen, the alcohol, owing probably to a slight loss from evaporation, is further reduced. The total solid matter is of course less, as all excess of yeast has been removed by the admirable filtering apparatus.

Absolute alcohol	0·21	per cent. by weight
Equal to absolute alcohol	0·26	„ „ „ volume
Equal to proof spirit	0·460	„ „
Total solid matter	0·120	„ „
Mineral matter	0·027	„ „

Samples of the liquor before it passes to the ground floor, where it is simply aerated, were next submitted to analysis, and the following results were obtained. The total solid matter is seen to rise to more than 1 per cent. As evidenced by the Fehling test, it consists of inverted sugar, added, however, in the form of pure cane sugar during the finishing process. The alcohol is exactly the same as in the last sample.

Absolute alcohol	0·21	per cent. by weight.
Equal to absolute alcohol	0·26	„ „ „ volume.
Equal to proof spirit	0·46	„ „
Sugar	1·25	„ „
Hop and other extractives	0·12	„ „
Total solid matter	1·37	„ „
Mineral matter	0·027	„ „

Finally, the bottled product, just as it leaves the brewery, was examined, and the following are the results:—

Absolute alcohol	0·32	per cent. by weight.
Equal to absolute alcohol	0·40	„ „ „ volume.
Equal to proof spirit	0·70	„ „
Sugar	1·42	„ „
Hop and other extractives	0·12	„ „
Total solid matter	1·54	„ „
Mineral matter	0·027	„ „

The process of fermentation has been so regulated, it is evident, as to reduce the alcohol to a minimum amount. Strictly speaking, Kop's ale cannot be called absolutely non-alcoholic, although practically it is so; but in view of the exceedingly small quantity it contains, it would be perfectly true to describe it as non-intoxicating. Regarding ordinary ale, to contain, say, 3½ per cent. of absolute alcohol, one would require to drink about ten times more Kop in order to ingest the same amount of alcohol. An average person does not ordinarily drink more than a pint of alcoholic beer on a single occasion, and the amount of alcohol contained therein would represent a gallon and a quarter of Kop's ale according to the above analysis, so that the beverage may fairly lay claim to be absolutely non-intoxicating as regards alcohol.

The beer contained a slight excess of carbonic acid gas, to the extent of from 50 to 70 cc. at 15° C. and normal pressure in each pint bottle, while there remained in every volume of the liquid immediately after opening from 1·1 to 1·2 volumes of gas (CO_2). The gas was perfectly pure, as it was wholly absorbed by potash. It is interesting to add an analysis also of Kop's stout, in that the results, while showing the same amount of alcohol, also give evidence of the presence of malt, which is used in the form of burnt malt for colouring the liquor, just as with ordinary stout. Thus, as the total solid matter is higher, so the mineral constituents are correspondingly increased; they consisted largely of phosphate of potassium.

Absolute alcohol	0·42	per cent. by weight
Equal to absolute alcohol	0·53	„ „ „ volume
Equal to proof spirit	0·93	„ „
Total solid matter	1·67	„ „
Mineral matter	0·04	„ „

It is quite obvious that Kop's ale is not merely, as we at first imagined, a haphazard compound, but rather a carefully brewed product, the preparation of which is based on sound scientific principles. It has a right to the title of a non-intoxicating beverage, and forms an excellent substitute for ordinary ale, which it resembles in taste, colour, appearance, and composition. We must candidly confess that when we first tasted Kop's ale the impression we received was rather unfavourable; but, as with many other articles of diet, its character improves remarkably on acquaintance, and it comes to be really liked. It contains all the valuable volatile as well as the fixed constituents of the hop; and the hops used, as is the case with the other ingredients, are selected, as proved by our examination, from the best kinds. As already suggested, the character of the bitter is soft and delicate, having been toned down doubtless by the process of fermentation. Going through the latter process, too, it is not surprising that the bouquet or, as it is expressively if not elegantly put, "the nose," possessed by the liquid is equal to many kinds of excellent alcoholic beer. Kop's ale affords an excellent and satisfying drink in hot weather; and while it contains all the tonic and refreshing qualities of beer, it can never be accused of stealing a march upon the mental faculties. It keeps well, and, as our examination of samples some months old shows, no appreciable after-fermentation sets up. The public, and especially the teetotal public, may evidently drink Kop's ale with confidence; it contains nothing that is injurious, but is, on the contrary, a salutary and palatable beverage, possessing distinct tonic and stimulating properties by virtue of the choice ingredients which form the bases of its preparation.

MR. BALFOUR ON THE PRESS.

THE anniversary dinner of the Newspaper Press Fund has had many distinguished men as chairmen, who have acquitted themselves on the occasion with more or less felicity. But we doubt if any of them have ever signalised it by a more happily conceived or, in the best of all senses, a more liberal speech than the First Lord of the Treasury at the twenty-ninth recurrence of the symposium on Saturday last. He could not describe himself, as Mr. Disraeli did, when in 1874 he rose to be Prime Minister of England, as "a gentleman of the press," but he humorously admitted that "he had in his time supplied more 'copy' than he thought was either agreeable to the public or agreeable to himself." In the process, however, of supplying this "copy" he had brought himself so intimately into touch with every section and subsection of the body politic—had, in fact, come so closely to identify himself with that body in all its life, inner and outer—as to speak with special authority when he said that "the debt the public owed to the newspaper press of this country was one which it was hardly possible to exaggerate." This tribute he at once explained and justified by the fact that while, alone in Europe, British journalism is anonymous—that while, in other words, its champions in the daily and weekly arena enter the lists with visor down and merge their personality in their cause—it has also the highest standard of responsibility; that it discusses the problems coming up from day to day or from week to week with the most keenly present conviction that the public interest is paramount, and that whatever may be the temporary claims of party, so far as its individual advocacy is concerned, its rallying cry has ever been, "Let all men's good be each man's rule." It is, in fact, the reflex of those representative institutions it has so powerfully contributed to create, insomuch that, conducted in this sense and in this spirit, it has developed, as Mr. Balfour showed, into "at once the freest, the ablest, and the most patriotic press among all the nations of the world."

When Mr. Cobden, in an often-quoted and much-perverted phrase, said that he preferred a single copy of

Digitized by Google

the leading journal "to all the works"—he meant, of course, the one work—of Thucydides, he was not depreciating the mental power and the unapproachable language of the greatest of historians by comparison with the intelligence and the literary form of a particular number of *The Times* newspaper. He was simply taking that specimen of the journal as an "instantia prærogativa," as Bacon termed it, of nineteenth-century civilisation in its *ensemble*—as the handiest embodiment of the whole intellectual and moral outcome of that which "is wiser than Socrates and wittier than Voltaire—the People"; as, in a word, the fullest expression up to date of "the heir of all the ages, in the foremost files of time"—the English-speaking democracy. Tested by such a criterion, the humblest metropolitan or provincial daily is immeasurably ahead of the finest literary *chef d'œuvre*, ancient or mediæval, that can be adduced; but he would be a poor friend of contemporary civilisation who would read in the fact any other lesson than that of humility, acknowledging as he must that what he so proudly calls his own is his by inheritance infinitely more than by individual effort. As Bacon himself, in the *Novum Organum*, quotes approvingly from Phocion, "when the populace applaud you, ask yourself what fault you have committed," so must we recognise in the press not only a *censor morum*, correcting, refining, and sweetening "our lives from year to year," but a *ductor dubitantium* bringing popular reasoning to the touchstone of daily recurring fact—in the intellectual sphere dispelling illusions or beating down prejudices; in the moral sphere, redressing grievances or reforming abuses—till "from the illumination of many minds on many points truth begins to emerge," and "the thoughts of men are widened by the process of the suns."

Compare the England of the first quarter of the nineteenth century with England as it is in the fast waning days of that century, and let us ask ourselves to what force or forces we are mainly indebted for the mighty advance in all essentials of civilisation so visible around us. The answer can surely be but this—public opinion educating itself by daily recurring contact with fresh actuality; correcting itself by discussion and rediscussion, and, from such vantage ground gradually gained, commanding ever-wider horizons and acquiring juster views under a truer sense of proportion and fitness. And to what instrument does that ever-improving public opinion owe its opportunities and facilities for the advances it continues to make? Chiefly, as Mr Balfour showed, to the press—that all-receptive Dionysius ear which not a sound escapes; that most sensitive of mirrors on which the faintest breath or ripple of thought or emotion is registered for prompt and universal recognition. Not that the ear or mirror is always true, or that consequently the conclusions drawn from their reports are always just. On the contrary, the reverse is far too often the case, and error is apt to be diffused and prejudice fostered by the very means which should be their proper antidote. Imperfection is incident to all things human, and the more complex the instrument or the more complicated the task it is put to, the greater the risk of its getting out of gear and turning out a defective product. But rightly used, the press contains within itself resources for its own correction and improvement, its authority becoming more recognised and more decisive in proportion as its facts are more carefully sifted and its conclusions more impartially drawn—in a word, in proportion as it becomes more scientific.

It is to the educating power of expert, particularly of scientific journalism, that we must look for the perfecting of this great instrument of civilisation. Manifestly the data on which such a specially trained press forms its conclusions are more rigidly guarded, and, *pro tanto*, the conclusions themselves are logically sounder than is possible in the vaguer, more loosely organised sphere of general politico-social discussion. Take any controverted matter in which the medical journalist, for example, has to join issue with his political compeer, and compare the precision of the criteria the former appeals to with the fluctuating standards set before the latter. We could, in point, adduce instance upon instance of the disadvantage under which the general journalist labours from his unfamiliarity with scientific processes or his ignorance of the value to be given to conflicting groups of data. He reasons rightly enough, for, as Cardinal Newman has lucidly shown, there are more false facts in the world than false deductions from them; but he has had to accept, with inadequate sifting, the materials of his induction and the inept and unconvincing result is all too apparent. Indeed, the action of the non-scientific press is responsible for the propagation of much that is unsound, and, when it affects legislation, positively mischievous. Within the last year or two we have seen tentative and but partially divulged proposals in therapeutics eagerly caught up by the non-professional press, a popular *furore* set on foot, the hand of the discoverer forced, and a premature application of his method put in practice, with the inevitable results of failure, disappointment, and the scepticism of reaction. Well might Koch contrast the conditions under which Jenner worked out his salutary innovation with those meted out to him when on the threshold of his own. The eighteenth-century pathologist worked in an atmosphere of non-publicity; he had ample leisure to test his plan, to subject it to every possible experiment, and to have it thoroughly matured and guaranteed against failure before submitting it to the world. His nineteenth-century counterpart had barely indicated the first lines of his proposals when they were seized upon by a sensation-mongering press, and so manipulated before the public that in self-defence, as a humanitarian, as well as a scientist, as he had to give them forth when ill-prepared for clinical application, till the gratitude prematurely showered upon him changed rapidly into a tempest of disparagement, if not obloquy, under which he retired to the seclusion of his laboratory, determined to let nothing escape him till it was ripe for professional appreciation and use. Such and similar experiences will inevitably leave their impression on the public, till it gradually gets educated up to the standard set before it by scientific or expert journalism, and the intrusion of the non-professional newspaper into fields altogether alien to it becomes a thing of the past. The reforms in which THE LANCET, when it did not actually initiate them, had so prominent a share were those in which it could speak with the authority inseparable from scientific vantage ground and professional prestige. Its memorable crusade against food adulteration—to instance one out of many—could never have been carried out to its issue in salutary legislation but for its appeal to the findings of the chemical analyst and its readiness to submit its charges to the test of the laboratory. The standard of journalistic integrity it thus set up is what, when more widely diffused and more practically complied with, must correct the besetting sin so delicately glanced at in Mr. Balfour's address to his audience of publicists. The non-acceptance of statements till thoroughly sifted and verified, the suspension of judgment till the facts on which it must form itself are fully and impartially before it, the apportionment of praise or blame in accordance with the precept of the Apostle—ἀληθεύειν ἐν ἀγαπῇ—such are among the conditions by which the press will make its power more and more beneficially felt and minimise the evils whereby that power has not seldom been impaired.

THE ELECTRIC LIGHT IN MEDICINE.

THE death was recently announced from Vienna of Josef Leiter, the well-known instrument maker of that city. The event recalls a stormy controversy, by which some years ago the attention of physicians and surgeons was directed to the gradual evolution of expedients for illuminating the less accessible of the body cavities. The movement had its commencement with the century, and attained its full development with the production of Leiter's cystoscope in 1887. The possibility of throwing light into the bladder was first conceived by Bozzini, who in 1805 exhibited his "light conductor." The contrivance failed to hold its ground, but the idea survived. In 1845 Mr. Avery, of Charing-cross Hospital, constructed a bladder speculum, in which the light was derived first from candles and afterwards from a benzene lamp. In 1853 Désormaux laid the first recognised endoscope before the Paris Academy of Medicine, and within a few years the project was taken up and many notable improvements effected by Cruise of Dublin and by many others, both in this country and abroad. The introduction of the electric light, as was

Digitized by Google

natural, gave a fresh impulse to invention, and marks an entirely new departure. It became possible, in theory, to dispense with the reflector and to substitute for the external lamp a source of direct illumination. At a very early period Schramm of Dresden devised his diaphanoscope. This was a lamp carrying a platinum loop at white heat. It was introduced into the uterus, and its object was to make the condition of the ovaries visible through the abdominal walls. Julius Bruck, a dentist of Breslau, enjoys the credit of having first employed the platinum loop in medicine. He had been an assistant to Schramm, and may possibly have borrowed the idea. In 1867 Bruck exhibited a stomatoscope which obtained some notoriety, and later a diaphanoscope for examining the rectum and bladder. These were quickly followed by Trouvé's polyscope, and Hedinger's ear speculum. The principle of all these instruments was the same. A loop of glowing platinum was enclosed in a small glass bulb, and the great heat generated was controlled by a surrounding cylinder of flowing water. The apparatus was necessarily cumbersome, and unceasing efforts were made to simplify it. In 1876 Dr. Nitze projected an instrument for illuminating the bladder, urethra, and larynx. He entrusted its execution to Deicke of Dresden, the lenses and prisms being executed by Bé öcke of Berlin. From their joint labours resulted the Nitze-Deicke endoscope. This proving unsatisfactory, Nitze next had recourse to Leiter. The constructive skill of the latter triumphed over the difficulties and the Nitze-Leiter cystoscope acquired a world-wide renown. Differences ensued between Nitze and Leiter, and their rival claims have not quite been settled. Leiter, now working alone, continued to effect further improvements in the cystoscope, and the perfection by Swan and Edison of the incandescent lamp found him ready to adopt the enormous advantage which it offered him. There was no longer need of the circulating stream of water. The instrument was simplified in many ways, and Leiter's cystoscope, when it appeared in 1887, was pronounced by competent authority to be the realisation of a century's dream. Shortly before the death of the instrument-maker Dr. Lewandowski published an admirable work upon "The Electric Light in Medicine," and he accorded a graceful tribute to Leiter's zeal and ingenuity. Leiter's name has become a household word of medicine in connexion with the tubes which are used in every hospital for the control of surface temperatures. It is another instance of the fact so often illustrated that to supply the commonest wants confers the widest and most lasting distinction. Beyond this, however, the Austrian instrument maker has a claim to the gratitude of science founded upon the distinguished part he played in promoting some of the most notable advances of a progressive age.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 7015 births and 3987 deaths were registered during the week ending May 14th. The annual rate of mortality in these towns, which had declined in the preceding three weeks from 21·8 to 19·7 per 1000, rose again last week to 20·4 In London the rate was 19·5 per 1000, while it averaged 21·0 in the thirty-two provincial towns. The lowest rates in these towns were 12·8 in Croydon, 13·0 in West Ham, 13·7 in Portsmouth, and 15·0 in Nottingham; the highest rates were 25·0 in Sheffield, 26·4 in Blackburn, 26·8 in Preston, and 28·1 in Wolverhampton. The 3987 deaths included 538 which were referred to the principal zymotic diseases, against 527 and 541 in the preceding two weeks; of these, 222 resulted from measles, 160 from whooping-cough, 58 from scarlet fever, 38 from diphtheria, 36 from diarrhœa, 20 from "fever" (principally enteric), and 4 from small-pox. No fatal cases of any of these diseases occurred last week in Gateshead; in the other towns they caused the lowest rates in Brighton, Norwich, Leeds, and Newcastle-upon-Tyne, and the highest rates in Manchester, Sunderland, Birkenhead, and Preston. The greatest mortality from measles occurred in Birkenhead, Manchester, London, Leicester, Liverpool, and Birmingham; from scarlet fever in Huddersfield, Cardiff, and Preston; from whooping-cough in Hull, Blackburn, Preston, Derby, Salford, Sunderland, and Birkenhead; from "fever" in Plymouth; and from diarrhœa in Preston. The 38 deaths from diphtheria included 24 in London, 2 in Cardiff, 2 in Birmingham, and 2 in Nottingham. Three fatal cases of small-pox were registered in London, and one in Liverpool, but not one in any other of the thirty-three large towns; 73 cases of this disease were under treatment in the Metropolitan Asylum Hospitals, and 13 in the Highgate Small-pox Hospital, on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1592, against 1408 and 1484 on the preceding two Saturdays; 232 new cases were admitted during the week, against 177 and 200 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 389 to 297 in the preceding three weeks, rose again to 304 last week, but were 40 below the corrected average. The causes of 67, or 1·7 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Cardiff, Oldham, Newcastle-upon-Tyne, and in twelve other smaller towns; the largest proportions of uncertified deaths were recorded in West Ham, Birmingham, Nottingham, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·3 and 21·4 per 1000 in the preceding two weeks, further rose to 22·8 during the week ending May 14th, and exceeded by 2·4 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·4 in Leith and 14·9 in Greenock to 22·3 in Perth and 27·6 in Glasgow. The 635 deaths in these towns included 32 which were referred to measles, 24 to whooping-cough, 8 to "fever," 8 to diarrhœa, 6 to diphtheria, 2 to scarlet fever, and not one to small-pox. In all, 80 deaths resulted from these principal zymotic diseases, against 70 and 65 in the preceding two weeks. These 80 deaths were equal to an annual rate of 2·9 per 1000, which almost corresponded with the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had increased in the preceding three weeks from 15 to 22, further rose last week to 32, of which 31 occurred in Glasgow. The deaths referred to whooping-cough, which had risen from 22 to 30 in the previous three weeks, declined to 24 last week, and included 14 in Glasgow, 4 in Aberdeen, and 3 in Edinburgh. The 8 fatal cases of "fever" exceeded those recorded in any recent week, and included 5 in Dundee. The deaths from diphtheria, which had declined from 10 to 1 in the preceding four weeks, rose again to 6 last week, of which 2 occurred in Glasgow and 2 in Greenock. The 2 fatal cases of scarlet fever were recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had declined in the preceding three weeks from 163 to 126, rose again last week to 140, and were within one of the number in the corresponding week of last year. The causes of 67, or nearly 11 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 43·9 and 33·0 per 1000 in the preceding two weeks, further declined to 31·0 during the week ending May 14th. During the first six weeks of the current quarter the death-rate in the city averaged 34·6 per 1000, against 20·1 in London and 19·8 in Edinburgh. The 208 deaths in Dublin during the week under notice showed a decline of 13 from the number in the preceding week, and included 24 which were referred to measles, 3 to whooping-cough, 1 to "fever," 1 to diarrhœa, and not one either to small-pox, scarlet fever, or diphtheria. In all, 29 deaths resulted from these principal zymotic diseases, equal to an annual rate of 4·3 per 1000, the zymotic death-rate during the same period being 3·3 in London and 1·2 in Edinburgh. The fatal cases of measles, which had been 20 and 40 in the preceding two weeks, declined again to 24 last week. The deaths referred to whooping-cough, which had been 11 and 4 in the previous two weeks, further declined to 3 last week. The 208 deaths registered in Dublin last week included 36 of infants under one year of age, and 37 of persons aged upwards of sixty years; the deaths of infants showed a slight decline, while those of elderly persons corresponded

Digitized by Google

with the number in the preceding week. Eight inquest cases and 6 deaths from violence were registered; and 61, or nearly one-third, of the deaths occurred in public institutions. The causes of 23, or more than 11 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

HOW GENERAL GORDON WAS REALLY LOST.

Surgeon-Captain T. H. Parke has a paper in the *Nineteenth Century* for the present month on this subject. He gives a brief but interesting, sketch of the stirring military events which occurred in Egypt from October, 1884, to the end of January, 1885. Khartoum fell on Jan. 26th. All that was required was, as the ill-fated hero had himself again and again pointed out, to let the enemy see by the presence of a few British soldiers that the long-promised relief was not all a delusion. The failure of the relief expedition is attributed by our author to delays at Metemmah, which was reached in sufficient time for the object of the expedition to have been effected. If a steamer had left Metemmah for Khartoum on the afternoon of the 21st she could have relieved Gordon on the 25th, and the fall of Khartoum would not have gone down to posterity as one of the blots of British history. The paper, apart from the light which it throws on the history and causes of that deplorable event, is interesting from the information it gives of the medical and surgical occurrences of the expedition.

DUBLIN BARRACKS BILL.

Mr. Brodrick has been elected Chairman of the Select Committee of the House of Commons to consider the Dublin Barracks Bill The members, in addition to the Under Secretary for War, are: Sir Edward Hamley, Mr. Barton, Mr. T. M. Healy, and Dr. Farquharson. The Bill is "to enable the Secretary of State for the War Department to purchase certain lands in or near Dublin for the improvement of the Wellington and Beggar's Bush Barracks at Dublin."

Fleet Surgeon Patrick Keelan, R.N., M.D., F.R.C.S.I., who died on the 9th inst., at Craigmore, Holderness-road, Hull, became Surgeon in the Navy in March, 1859, Staff Surgeon in December, 1870, Fleet Surgeon in October, 1880, and retired in January, 1882.

ARMY MEDICAL STAFF.—Surgeon-Captain H. E. Dowse, Madras Command, has been transferred to the Rawul Pindi District; Surgeon-Captain B. J. Inniss has been posted for duty at the Station Hospital, Bangalore; Surgeon-Major J. T. Goggin has been appointed to the charge of the Station Hospital, Nusseerabad, Bombay Command.—The undermentioned Officers, on arrival from England, have been posted for duty as follows, in the Bombay Command:—Surgeon-Captain C. A. P. Mitchell, to Poona; Surgeon-Captain C. Birt, to Bombay, for Aden; Surgeon-Captain J. D. Day, to Bombay.—The following Officers have arrived in India for duty: Surgeon-Captains M. F. Macnamara, T. O. H. Hamilton, H. J. Barrett, and E. M. Williams.—Surgeon-Lieutenants J. D. Alexander and C. B. Lawson have been posted to the Station Hospital, Western Heights, Dover; Surgeon-Captain J. J. C. Watson to the Second Station Hospital, Aldershot, for duty.—The undermentioned Surgeon-Lieutenant-Colonels retire on retired pay (dated May 18th, 1892):—Charles Edward Dwyer and William Cameron Grant, M.B.

ARMY MEDICAL RESERVE OF OFFICERS. — Surgeon-Captain G. W. Murphy, M.B., to be Surgeon-Major (dated May 18th, 1892).

NAVAL MEDICAL SERVICE.—Deputy Inspector-General of Hospitals and Fleets Adam Brunton Messer, M.D., has been promoted to the rank of Inspector-General of Hospitals and Fleets in Her Majesty's Fleet (dated April 27th, 1892).—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Surgeon Geo. Lowbridge Baker has been placed on the Retired List of his rank (dated May 12th, 1892).—The following qualified candidates for the Naval Medical Service have been appointed Surgeons in Her Majesty's Fleet:—Samuel Ingleby Oddie, M.B., Henry Baker Hall, M.B., Henry William Gordon Green, Thomas Edward Honey, M.D. Edward Butler Pickthorn, George Thompson Bishop, Edgar Fairbank Mortimer, Beauchamp Fredk. Parish, Frederick Albert Capps, and Charles Frank Warren (all dated May 11th, 1892).—The following appointments have been made at the Admiralty:—Fleet Surgeons: Robert Grant, M.A., M.B., to the Portsmouth Division Royal Marines (dated May 15th, 1892); George Maclean, M.A., B.A., to the *Royal Sovereign* (dated May 31st, 1892). Staff Surgeons: W. G. Jack to the *Bellona*, Charles E. Geoghegan to the *Audacious*, and Samuel Keys to the *Porpoise* (all dated May 18th, 1892); Standish F. O'Grady to the *Ganges* (dated May 19th, 1892). Surgeons: B. R. Clarke to the *Triton*, W. Eames to the *Wildfire*, F. W. Collingwood to the *Vivid* (additional), and William W. Jacobs to the *Royal Sovereign* (all dated May 31st, 1892).

VOLUNTEER CORPS.—*Artillery:* 3rd Durham (Western Division, Royal Artillery): John Macdonald, M.B., to be Surgeon-Lieutenant (dated May 14th, 1892).—*Rifles:* 6th Middlesex (St. George's): Surgeon-Lieutenant F. E. Fenton to be Surgeon-Captain (dated May 14th, 1892).

Correspondence.

"Audi alteram partem."

IDENTIFICATION OF TUBERCLE BACILLI IN SPUTUM BY A NEW AND SIMPLIFIED PROCESS.

To the Editors of THE LANCET.

SIRS,—Since the discovery of the tubercle bacillus every year has furnished forth one or more methods of demonstrating it, and about twenty methods are before the public at the present day. My only reason for adding further to this number is the simplicity of my procedure. In order to distinguish the bacillus of tubercle from others existing in sputum, or in tissues, it is usual to employ acids as decolourising agents. I have found, however, that whereas most bacteria lose the stain very rapidly in boiling water, the tubercle bacillus retains it for a much longer period, sometimes over five minutes.

The following is my process:—The sputum is dried and fixed on a cover glass, and stained with hot carbol fuchsin in the usual manner. The cover glass is then moved to and fro in water at a temperature between 208° and 212°F. during one and a half to three minutes, one minute often sufficing. The specimen may now be mounted either in water and examined microscopically, or may be subjected to any double staining process which may seem necessary. In order to obtain good results the film must be as thin as possible, and evenly distributed, as otherwise any little lumps which may exist will retain the colouring matter even longer than the tubercle bacilli. Sometimes the decoloration of the bacilli, from causes unknown to me, takes place more rapidly than usual, and therefore it is best to continue the process only until the cover glass presents a faint rosy gleam. This method is probably not applicable to the examination of tissues on account of the coagulation and imbibition that it produces. On the other hand, the method may be most successfully employed for the identification of the lepra bacillus. I hope later to be able to give further information on this subject. The results obtained are not quite so perfect as those produced by some other methods, and I bring forward the hot-water process, not as a laboratory method, but one for use at the bedside, and the object of my communication will have been fully realised if I have brought before the general practitioner a method by which he may easily and rapidly determine the presence or absence of the tubercle bacillus.—I am, Sirs, yours truly,

Cairo, May, 1892. P. KAUFMANN.

*** The great advantage of this method, if it answers as well or nearly as well as the methods now in use, is its simplicity, as boiling water may often be obtained when acids are not to hand. There is, however, another possible advantage. The water will not continue to act when it is cooled, and in all probability the staining will remain more permanent than where acid is used, as this, unless very carefully removed or neutralised, continues to decolorise even after the specimen is mounted.—ED. L.

INCREASE OF SMALL-POX.

To the Editors of THE LANCET.

SIRS,—As you will probably call attention to the increased number of cases of small-pox notified in this district during the past week, I would take this opportunity of stating briefly some facts in connexion therewith. At the end of February and beginning of March a number of cases occurred, and were all traced to a girl whom it was found had suffered from small-pox some few weeks previously, and who had not been under medical treatment except on one occasion in the early stage of the disease, before its distinctive characters were sufficiently clear to enable the medical man to make a correct diagnosis. From this girl, as a source of infection, I have been able to trace upwards of forty other cases. On the immediate isolation of all cases discovered the outbreak seemed to subside, but ten days ago another batch of cases occurred, and have been traced to a case similar in many respects to the first, except that in the second girl's case no medical man had been consulted at all, and the girl was found to have been suffering for three or four weeks in a tenement house containing forty adults and seventy children, twenty of whom were unvaccinated. Several interesting questions have been raised in connexion with both outbreaks, but I would at present draw attention to two. First is the difficulty existing in a neighbourhood containing very poor persons who do not call in the help of any medical man, not even the parish medical officer, in time of sickness, unless it interferes with the ability to work, or is likely to be dangerous to the individual. In both outbreaks it was necessary, in order to detect fresh cases, to visit daily the families living in houses adjoining those in which small-pox had appeared; by this means were the original cases discovered. That it is possible for cases of small-pox to exist for weeks hidden in a district is a condition of things dangerous not to the district only, but to the whole of London, and does not appear to have been taken into account in the Public Health Act; the only way to deal with it seems to be in a regular house-to-house visitation, by the medical officer of health examining every person; but before his suspicions are aroused a case may have existed sufficiently long to infect a widespread area.

A second matter which has been forcibly brought under my notice is the difficulty of obtaining speedy isolation of suspicious cases. The Metropolitan Asylums Board have no power to make provision for cases of this description, and several persons have had to remain in tenement houses until the disease was sufficiently distinct to enable the medical attendant to come to a decision as to the nature of the disease. Some of these suspicious cases in houses in which small-pox had occurred turned out not to be small-pox; but this was not so in regard to the majority, who in the meantime were acting as sources of infection. There should be some provision made for placing in quarantine cases of this description, as the absence of such interferes to a great extent with the endeavours of the local authority to prevent the spread of the disease; there is need, moreover, for some consolidation of authorities in regard to small-pox prevention, for at present there are more or less concerned therein no less than five bodies—viz., the Local Government Board, the County Council, the vestry or local board, the Metropolitan Asylums Board, and the guardians.—I am, Sirs, yours faithfully,

FRANCIS J. ALLAN,
Medical Officer of Health, St. Leonard, Shoreditch.

May 17th, 1892.

THE HURDWAR FAIR AND CHOLERA.

To the Editors of THE LANCET.

SIRS,—The telegraphic news from India in *The Times* of the 16th inst. regarding the correspondence in the native press of the north-west provinces relating to the dispersion of the pilgrims at the Hurdwar fair owing to cholera is of far greater importance to the public health of India—and, indeed, the world—than we are apt to suppose; and on this account I trust you will kindly insert this letter. I have had opportunities—unequalled, I believe, by any other medical officer in India—of judging of the effects of this vast concourse of human beings, collected at the worst time of the year, in the place least suited for it, and themselves in a condition most unfitted to resist the fatal influences inseparable from these gatherings, and I can unhesitatingly state that the condition of Hurdwar and the roads leading from it in 1867 and 1879 was a disgrace to any Government, and infinitely more so to one which had an apparently fully equipped sanitary department. For weeks before the Hurdwar Fair the district arrangements of Saharanpur (that in which Hurdwar is situated) were completely upset, and to end in both years, as I know, in the unutterable failure witnessed at Hurdwar on April 13th in 1867 and 1879 would, one would have supposed, have been ample proof that something was necessary to prevent the recurrence of what seemed so impossible to prevent by local sanitation. But, no; the horrors of 1867 were repeated and intensified in 1879. I am, therefore, truly thankful to see that the Government have felt compelled to take the action they have done on the score of public health. Without doubt our annual treatment of the vast crowds which meet at Hurdwar on April 12th each year is enough to make the continental sanitarians put us out of court altogether in the matter of the spread of cholera, and the scenes enacted and repeated each year at Hurdwar for twenty years, as I know from 1864, were such as would never have been tolerated for one year in this country. In the absence of details of the present correspondence I will add no more, except to remark that it is little wonder to me that the sanitary authorities of the continent of Europe view with alarm much that we do with reference to the treatment of cholera outbreaks, after vast gatherings like those at Hurdwar, and hesitate to give us too free a hand on account of our vastly greater commercial intercourse.

I am, Sirs, yours truly,
ROBERT PRINGLE, M.D., Brigade-Surgeon.

Blackheath, S.E., May 17th, 1892.

INTESTINAL OBSTRUCTION.

To the Editors of THE LANCET.

SIRS,—In the report of a case of intestinal obstruction under Dr. Cousins, it is noted that the coil of intestine was blue, showing where it had been constricted. In examining the abdomen after fatal results of herniotomy, I have frequently noticed this condition, with an entire absence of other signs of general peritonitis, even when the period between the time of relief and death was sufficiently long to allow signs of peritonitis to develop. I have further seen in such cases that the discoloured coil lies at a distance from the part of the abdomen where it was constricted, and that the patient passed flatus before death. The explanation suggested is that the septic material penetrates the damaged wall of the intestine, intestinal movements spreading the material over a wide area. The natural inference to be drawn is that in cases of herniotomy where the condition of the gut is doubtful, opium ought to be administered early in full doses.—I am, Sirs, yours truly,

WILLIAM HORROCKS, F.R.C.S.Eng.

Bradford, Yorks, May 16th, 1892.

THE PHYSIOLOGY OF DREAMS.

To the Editors of THE LANCET.

SIRS,—Will you allow me also to express how interested I was not only in your annotation on Dr. Richardson's lecture at the Royal Institution, but also in Dr. Wilks's letter in your issue of to-day? I also was not present at the lecture, but hope to see it in the forthcoming number of the *Asclepiad*. The *Daily Telegraph*, in a leading article on what Dr. Richardson said, quotes him as stating that "all musical instruments dream after they have ceased playing, and a microphone will detect their dreams." This, to my mind, is a beautiful and pithy way of expressing the science and secret of dreams. The dreams of musical instruments can be proved by the tuning fork, the piano, the organ, or the violin, both by the detection of vibration set up by and lasting after actual playing, and from unobserved causes. These unobserved causes may be jolts and jars, wind, varying degrees of tension from temperature or atmospheric pressure, electrical currents, rusting or chemical action, friction from dust and insects, or even animals like mice. If instruments were possessed of minds they would dream these sounds and sighing vibrations in the periods of

Digitized by Google

rest between the real times. An impartial *résumé* of the many theories of dreams is given by Dr. Sully in the article on "Dreams" in the *Encyclopædia Britannica*, and also in the work on "Illusions" (International Science Series) by the same author. I may here say that the physiological theory there given completely accounts for all the phenomena of dreams except their visual aspect, or what Wundt calls "the light chaos." In your second volume for 1889 I suggested that the visual aspect was due to actual light being more or less perceived by the intellect during the sleeping state. That there is actual light developed in the body at all times is certain from the physical transformations of energy taking place, and from the presence of phosphorised fats, whether in the blood-corpuscles, nerve tissue, or brain substance. The chemistry of these phosphorised fats, which is very complex, can be studied in Dr. Thudichum's "Physiological Chemistry of the Brain," and also in a most interesting address on the cerebro-spinal system in the last number of the *Asclepiad*. Dr. Sully describes a dream he once experienced after trying to fall asleep by counting. The numbers took on visual form, and he saw them coming in endless procession, knocking and jostling against each other in most grotesque and comical fashion. Were these blood-corpuscles actually seen and mistaken for the numbers with which the mind had been engaged a moment previously?

I am, Sirs, yours faithfully,

Plumstead, May 14th, 1892. FRANCIS EDWARD CANE.

THE ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

To the Editors of THE LANCET.

SIRS,—Mr. W. G. Dickinson, in his letter published in your issue of the 14th inst., employs an expression "took offence" which, as applied to myself, scarcely meets the case. Will you therefore permit me to say that in my letter of resignation, dated April 15th, I stated that "I declined to forward to *any* professional man so insulting a communication" as that passed, in the unavoidable absence of both Dr. Steele and myself, on April 12th, and received by me for transmission to the solicitor on April 14th? This was one of my two immediate reasons, and I should again decline to forward, for any body of men, to any professional man a resolution that he be "forthwith informed that his services are no longer required." How would Mr. Dickinson regard such a proposal if the gentleman whose "services were no longer required" were himself and the dismisser a patient? Moreover, as to the plea of the committee's "desiring to ascertain the extent of their liability as soon as possible," they had already, at a meeting at which the solicitor was present, on April 6th—i.e., only six days previously—requested him to forward his bill of costs to one of themselves as soon as feasible, and did not then breathe a word as to this prospective curt dismissal. Declining, therefore, to forward the resolution of April 12th, my resignation followed as a matter of course; for I did not wish the committee to be placed in the painful position of having to deal with a rebellious secretary. My other decisive reason, which I also stated in my letter of resignation, was that I strongly objected to the manner in which the Association's Minute-book had been obtained and subsequently withheld from its lawful custodian, myself, the acting secretary.

With regard to the resignation of my colleague, Dr. Steele, I hear from him that the grounds stated by Mr. Dickinson formed but a portion of the reasons which influenced Dr. Steele in forming his decision, although anxious to assist the committee in any possible way, and that he likewise declined to forward to the solicitor the resolution above referred to. Mr. Tait was naturally informed by me of the above chapter of events, and this is probably one, but by no means the "sum total," of the matters to which he alludes; though neither the solicitor, nor my co-secretary, nor myself was aware of his intention to write you, until, in common with all your readers, we saw his letter in your columns of the 7th inst. It is no doubt a compliment to Mr. Lawson Tait that his "advice" should be considered by Mr. Dickinson to have outweighed the better judgment of the rest of the Committee, but it now appears to be met by them with a recognition as marked as that shown to their other advisers.

Mr. Dickinson now having publicly occupied himself with the question of the recent changes in the officering of the Association, perhaps he will go a little further and induce the Central Committee to assemble and officially receive the month-old resignation of two honorary secretaries who have served that body for over seven years.

I am, Sirs, your obedient servant,

W. A. ELLIS,
Late Honorary Secretary of the Association of Members of the Royal College of Surgeons of England.

May 18th, 1892.

THE NEW CURRICULUM AND THE SCALE OF FEES.

To the Editors of THE LANCET.

SIRS,—Rumour has many tongues, and not all of them are truthful. It would be interesting to know what truth there is in the rumour that when the new prospectuses of the eleven London schools for the coming session are issued it will be found that there is the same wretched underbidding of each other in the matter of fees for medical education as in the years gone by. We all know that in view of the five years' curriculum there have been meetings of the deans to consider the question of fees, and that there has been a widespread feeling that the opportunity should not be lost of raising the London fees to something like an adequate sum, and at the same time also of putting the fees of all the schools on an equal footing. Is it true, however—is it possible—that this excellent scheme has been frustrated by the action of one of the smaller schools, by one which surely ought to have known better, by independently and, it is said, irrevocably fixing its new scale of fees at a contemptibly small increase upon that of last year; that others of the smaller schools feel it in the circumstances impossible to raise their fees to the sum which they had wished, and which had been advocated and will be adopted by the large schools; and that yet others of the schools are even descending still lower, and are proposing an addition to their fees, already too low, which is simply ridiculous? I name no names and no amounts, but if rumour be true we shall have three various and unmeaning scales of fees in force at our eleven London schools, instead of one and the same at all of them, for which many had wished, and for the consummation of which a unique opportunity had at length arisen. Is it too late even now for the deans to arrange and finally settle that we, the constituents of the one great school of medicine in London, shall act together and in unison, that we shall raise the fees for medical education to a scale somewhat commensurate with those of other professions, and that an era shall be begun when the various schools will show that they individually seek to attract students by the quality of their teaching, rather than by the deplorable system of underbidding which to many of us is disgusting in the last degree?

I am, Sirs, yours faithfully,

May 11th, 1892. OLIM DECANUS.

DEATH UNDER CHLOROFORM.

To the Editors of THE LANCET.

SIRS,—A case of death under the influence of chloroform having unfortunately occurred here, I think it right to report it. A boy aged eleven years was recommended to have adenoid growths removed from his naso-pharynx. He was a pale, anæmic child, with no disease of lungs or heart. He had been told to have nothing to eat after his breakfast at 7.30 A.M. on the 14th ult. (being an out-patient); and at 1.15 P.M. I was asked to give chloroform. He took it slowly, not breathing well, but with no difficulty or struggling. His pupils being slightly contracted, and the cornea insensitive, the operation for removal of the growths, by Loëanberg's forceps, was commenced. There was not much hæmorrhage or coughing, and the operation was just finished. While sponging out the pharynx, however, the respiration was noticed to stop for a second, but commenced again, there being slight cyanosis about the eyes, though the lips remained of good colour. The gag was at once removed. The pulse was imperceptible. On auscultating the chest no heart sounds were audible, though the breath sounds could be well heard and air was entering

Mr. [illegible] now having publicly occupied himself [illegible] the question of the recent contests in the University [illegible] perhaps he will go a little further and [illegible] Council or Committee to assemble and officially [illegible] the representatives of two honorary secretaries who [illegible] served their body for over seven years.

I am, Sir, your obedient servant,

W. A. [illegible]

[illegible]

May [illegible] 1892.

THE NEW CURRICULUM AND THE SCALE OF FEES.

To the Editors of THE LANCET.

[illegible] Examiner has many forgives, and not all [illegible] are thankful. It would be interesting to know what [illegible] is in the rumour that when the new prospectuses [illegible] are issued by the London schools for the coming session it will be found that there is the same wretched [illegible] of each other in the matter of fees for [illegible] as in the years gone by. We all know [illegible] one of the five years curriculum there have been [illegible] efforts to consider the question of fees, and [illegible] has been a widespread feeling that the opportunity [illegible] be used of raising the London fees to some [illegible] same scale, and at the same time also of [illegible] the schools on an equal footing. It [illegible] [illegible] if possible—that this excellent scheme [illegible] frustrated by the action of one of the smaller [illegible] which surely ought to have known better, [illegible] it was said, irrevocably bound to [illegible] a contemptibly small increase upon that [illegible] at present charged by the smaller schools. [illegible] that there of the smaller schools feel it [illegible] impossible to raise their fees to the [illegible] which was resolved, and which had been advocated [illegible] by the large schools; and that yet there [illegible] are even descending still lower, and are [illegible] to their fees, already too low, which [illegible] I name no names and no amounts, [illegible] be true we shall have three various and [illegible] fees in force at our eleven London [illegible] and the same at all of them, for which [illegible] and for the consummation of which [illegible] had at length arisen. Is it too late [illegible] to arrange and finally settle that we, [illegible] of the one great school of medicine in [illegible] act together and in unison, that we shall [illegible] for medical education to a scale somewhat [illegible] with those of other professions, and [illegible] from which the various schools will [illegible] seek to attract students by the quality [illegible] rather than by the deplorable system [illegible] which seems to many of us is disgracing [illegible]

I am, Sir, yours faithfully,

OLIM DISCIPULUS.

[illegible]

DEATH UNDER CHLOROFORM.

To the Editors of THE LANCET.

SIRS,—A case of death under the influence of chloroform occurred here, I think it right to state, unfortunately, yesterday week. A boy aged eleven years was [illegible] for the removal from his nose [illegible] a polypus. The child, with no disease of [illegible] was, as a rule, a healthy child, with no [illegible] seemed to me to have nothing to contraindicate [illegible] I saw on the 14th inst. (being an out patient) [illegible] M. I was asked to give an opinion. He [illegible] not breathing well, but with no [illegible] His pupils being slightly contracted [illegible] The operation for removal of the [illegible] forceps, was commenced. The [illegible] by Lockhart's forceps, was [illegible] much hæmorrhage or crushing [illegible] was just finished. While operating on the [illegible] the respiration was noticed to stop [illegible] ever, the respiration was noticed again, there being slight [illegible] recovered again, there being slight [illegible] The pupils remained of good colour. [illegible] that the eye remained perceptive. [illegible] recovered. The pulse was imperceptible, [illegible] the chest no heart sounds were audible, [illegible] sounds could be well heard and air was [illegible]

freely. Steps were at once taken to stimulate the heart—amyl nitrite inhalation, injection of ether hypodermically—and hot towels were applied to epigastrium and head. Partial inversion of the child was tried, and artificial respiration was continued for three-quarters of an hour. The breathing having ceased some minutes after stoppage of the pulse, the child gave only one or two short gasps and showed no more signs of life. The chloroform used was that manufactured by Macfarlan and Co., and the quantity given was only two drachms, the administration having lasted but from five to ten minutes. The portion remaining in the bottle has been sent to Professor Ramsay, of University College, for analysis. My colleague, Mr. H. G. G. Cook, the house surgeon, performed the operation. An inquest was held, and the jury returned a verdict of "Accidental death from syncope during the administration of chloroform." Unfortunately a post mortem examination was not obtained, the coroner not having ordered it to be performed.

I am, Sirs, yours truly,

R. C. M. COLVIN SMITH, M.B., B.C. Cantab.

Victoria Hospital, Chelsea, May 18th, 1892.

THE INTERIM REPORT OF THE VACCINATION COMMISSION.

To the Editors of THE LANCET.

SIRS,—The fifth report of the Vaccination Commission must have come as a thunderclap to those public vaccinators who have not been watching the course of events. One of your daily contemporaries to-day in a short leader says:—"The conduct of the Local Government Board in reference to this matter has not been wise, in advising boards of guardians after a fashion very similar to the recommendation now made by the Royal Commission." In regard to vaccination, the Local Government Board and the public represent the devil and the deep sea. I have been a public vaccinator for a number of years, and formerly earned a respectable sum in fees and grants. I was then vaccinating by three insertions, and in every way satisfied the requirements as to the area of foveation. A few years ago I was directed to make four insertions. After representing the inevitable result, I complied. The attendance at most of the stations has fallen off, and my principal one is nearly deserted for the surgery of the private practitioner who will vaccinate in two places, or even in one. If the object of the Local Government Board was to obtain more efficient vaccination, it has utterly defeated itself, as many parents, in addition to those who paid for scanty insertions, decided against the operation altogether, and no prosecutions followed.

The Local Government Board ought to have obtained an Act of Parliament requiring every certificate to state that four insertions of lymph had been made, and then they might have begun with the public vaccinators. In the present political situation they were too wise, no doubt, to attempt such a task.

I am, Sirs, yours faithfully,

May 12th, 1892. PUBLIC VACCINATOR.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LIMITED.

To the Editors of THE LANCET.

SIRS,—One of the greatest legal hardships affecting medical men is, that any pauper can issue a writ on the most trifling of pretexts, and so put not only one of us, but any one, to great expense. Even a man with some means can harass a medical man with proceedings, bringing a case to the verge of trial, and then, by paying some £30 or £40, withdrawing it, probably costing the unfortunate doctor one to two hundred pounds for unrecoverable costs. Combination has several advantages: First, a protection society places, through its organisation, at the command of any medical man, for a payment of 10*s.* a year, a staff of skilled experts, used to dealing with all kinds of cases of difficulty, whether legal, surgical, or medical, likely to arise in the practice of his profession. Such a society reduces to a minimum the enormous expense and inconvenience caused to a man who has to leave his business and work up his defence properly. Secondly, by the society at once offering to receive on his behalf the threatened process and entering an appearance, and preliminarily investigating the matter, the doctor concerned is saved great expense and anxiety. Thirdly, the mere receipt of an official letter in reply to the threat of proceedings in blackmailing cases (which are more frequently of occurrence than would be imagined) generally prevents further action being taken. The blackmailer seeks to isolate and terrify his intended victim; and the facts that he has taken counsel with others, and that the would-be blackmailer finds that he has to deal, not with one person, but with a powerful association, like the Medical Protection Society, having its head-quarters in London, and associated with some of the most eminent London and provincial practitioners, are almost certain to make the attacker stop proceedings.

I have seen great evils arise from cases being tried in country towns. I hope our council will decide, whenever it is possible, to have country cases in which our society is interested dealt with in the London Courts, where the attendance of experts would be easy to obtain, and, what is most important, all local influence and feeling would be excluded. Starving the defence is a very bad policy; that error, I am sure, our council will not fall into. In one case within my cognisance a respected practitioner, owing to these two causes—local prejudice and the absence of experts,—was mulcted in costs &c. amounting to nearly £600. I am sure that had the case been tried in London the action would either have been abandoned or decided very differently.

I am, Sirs, yours very faithfully,

May 16th, 1892. GEO. B. MEAD, Hon. Sec.

THE TREATMENT OF THE NASO-PHARYNX.

To the Editors of THE LANCET.

SIRS,—In the very kind notice of my recently published work which appeared in your columns reference is made to two points of considerable practical importance. As those who read the review without perusal of the book may arrive at an erroneous idea concerning my views, you will, perhaps, kindly allow me to make an explanation. Your reviewer is perfectly accurate when he writes: "..... while he impresses upon the reader the theory that affections of the anterior nares and pharynx, when coexisting with middle ear disease, need only be treated in so far as they are producing direct symptoms." It has, however, appeared to me desirable to explain that the naso-pharynx is very specially excepted from this statement (p. 567). With regard to the connexion between atrophic nasal catarrh and laryngitis sicca, my own experience points to the existence of two varieties of the latter. One of them, the more common, occurs, so far as I have seen, independently of any nasal affection; while the other, less frequently met with, is practically identical with Baginsky's "ozæna laryngis," described on p. 119.—I am, Sirs, yours faithfully,

Edinburgh, May 14th, 1892. P. MCBRIDE.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Hospital Saturday in Liverpool.

SATURDAY, the 14th inst., was observed this year as Hospital Saturday. As might have been expected in so business-like a community as this is, the committee have profited by past experience, and have resolved to rely more upon the amounts raised by weekly or monthly contributions all the year round, in workshops and other large centres of working men, than in that raised by boxes deposited on a certain day, to be called for a few days later. The results of this latter mode of collection have been found insufficient to justify the expenditure. A concert is also to be given in St. George's Hall on the 23rd inst., under distinguished patronage, for the benefit of the medical charities, and there is every reason to expect a "bumping house" and a substantial addition to the Hospital Sunday Fund.

Crimes of Violence.

Lancashire has for years past had an unenviable reputation for crimes of violence. Some years ago it took the form of what was locally termed "purring"—i.e., kicking

Digitized by Google

the unhappy victim with heavily shod boots or clogs till insensibility or even death supervened. More recently the mode of attack has been by knives, in the hands of gangs of youths calling themselves the High Rip Gang, in this city, and "scuttlers" in Manchester. As the practice of "purring" became obsolete after some exemplary sentences involving a long term of penal servitude, it is hoped that similar drastic measures may end this reckless use of the knife.

The Liverpool Royal Infirmary and Elections to Honorary Medical Offices.

An election will shortly take place of one assistant physician and two assistant surgeons to the Royal Infirmary, under greatly improved conditions over those which governed former elections. The electorate in these latter having been the trustees, each candidate was put to considerable expense for advertising, printing, &c. Worse than the expense was the necessity of having to canvass a large number of persons of both sexes scattered over a very wide area, involving very considerable labour, in addition to the humiliation involved in such a mode of election. Now all is happily changed, the elections in future being in the hands of an election committee sufficiently comprehensive to be beyond the power of a clique, and yet not large enough to be unwieldy. Any canvassing or advertising on the part of any candidate will disqualify him for election; but candidates may send copies of their testimonials, not exceeding a specified number, to each member of the election committee. For the three vacancies there are already a number of eligible candidates, and the result of this first election carried out on the new mode will be watched with much interest.

Coffee Drinking.

Some years ago it was suggested that prizes should be given for the best-made cup of tea or coffee as much as for the best show of fruit or flowers. It is to be regretted that the suggestion was not more capable of being put in practice, since the tasting of many specimens and the awarding of the prize would involve insuperable difficulties. It is satisfactory, however, to notice both an increased demand for and an equally increased supply of *cafés* where excellently made coffee can be had at very moderate charges. To many of the daily increasing number of total abstainers a cup of really good coffee is perhaps more wholesome, as well as more palatable, than a too free use of aerated waters; while many who are moderate drinkers would prefer coffee in the middle of the day, or at other times when on duty.

May 17th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Growth of Newcastle-on-Tyne.

THE report of our city engineer is an instructive document as showing the rapid growth of the place, which, in 1882, contained 20,600 houses occupied by 147,000 persons, while in 1892 the number of houses had risen to 26,800, and the population to 192,000, an increase of just 30 per cent. The increase in houses and population has taken place chiefly in the east and west-ends of the city, resulting in the formation of practically two new towns. The question of the housing of the poor has been endeavoured to be met by a scheme for the erection of lodging-houses for single men and women, and the city engineer hopes that the well-meant but short-sighted opposition to this proposal may not be pushed too far, or, he says: "You may find too late that what you can do voluntarily for from £15,000 to £20,000 may cost you under pressure from £80,000 to £100,000." He is no advocate of the pail system, but opposes it on economical and sanitary grounds, and quotes the example set by Manchester, where it is being at some expense abolished.

Newcastle Eye Infirmary.

The annual meeting of the Newcastle Eye Infirmary has been held; the Mayor presided, and referred to the good work done by the institution, which had been a recognised charity for seventy years, and had done in its time a large amount of useful work. Dr. Jeaffreson in his report said that nearly 3000 new patients had been treated, of whom 307 were in-patients, and that about 20,000 consultations had been held. Complaint was made of the inadequate support the institution received, and the financial report showed that the ordinary expenditure had exceeded the ordinary income by over £300. An instance was given in which an important manufacturing firm had sent in thirty-six patients for treatment and had given no subscriptions; some of these cases were very serious. Some of the workmen's committees who distribute their own collections are more liberal, but still there was room for improvement in this, as for fifteen guineas subscribed they been called upon to treat 188 workmen.

Middlesbrough and District.

A curious case of milk adulteration came up before the Middlesborough magistrates lately, in which the defendant was charged with adulterating milk with water to the amount of 7 per cent. It was urged that a cow by poor feeding might have its milk reduced to this extent, and that some day the magistrates might have to decide how far a cowkeeper was justified in watering the milk by adulterating the cow! Ultimately the excuse did not avail, and the defendant was heavily fined, with costs.—The annual meeting of the North Ormesby Cottage Hospital has been held and the report presented, which shows that the total number of in-patients is 517. The financial state of the hospital was satisfactory. — The medical officer of the Normanby Local Board, in reference to the high death-rate prevalent in the previous month—viz., 35·6 per 1000—states that this is abnormally high, and is chiefly due to an epidemic of measles. Scarlet fever had been reported, but was not fatal.

Carlisle and District.

Sunday, the 8th inst., was Hospital Sunday in Cumberland and Westmoreland, and collections were made in the churches and chapels on behalf of the medical charities. The following will participate in the fund: The Cumberland Infirmary, Carlisle Dispensary, Carlisle Fever Hospital, Silloth Convalescent Institution, and Workington Infirmary. The weather was fine, and the congregations considered up to the average of previous years.—There has been rather an alarming outbreak of typhus fever in the Finkle-street district of Carlisle; in all about eleven cases have been reported and removed to the Fever Hospital. The inspector reported that from one of the fever dens were taken six cartloads of dirt, rags, and bedding, old cushions, baskets, and cow's horns. Typhus fever is also reported as having broken out at Workington and Whitehaven. At the former town there has been a serious outbreak of measles, and the infant schools have been closed in consequence.

Langholm and its proposed Hospital.

A meeting was lately held at Langholm in support of a hospital to be erected for the treatment of infectious diseases in the district. Nothing, however, was decided. It was pointed out that the late Mr. Hope of New York, who had left £80,000 for the erection of a hospital in Langholm for those above the pauper class, had wished the hospital to be made available for infectious diseases as well; but as the bequest was the subject of litigation in New York it was considered it would be well in the meantime to watch and wait.

Sunderland.

Mr. A. E. Harris, medical officer of health, reports as to the excessive number of deaths during the last fortnight, 134, or an annual mortality of 26·35 per 1000; of these deaths, 33 were from respiratory diseases. The excessive mortality was attributed to the severity of the weather on the east coast. The only other town, he said, similarly situated to Sunderland was South Shields, which had also a high death-rate—viz., 26 per 1000. Dr. Squance, in his report as medical officer for the Sunderland rural authority, in his reference to influenza, says that, so far as could be estimated, about 3000 persons were attacked, but only one case proved fatal. The annual report of the Sunderland Nursing Institute has been held, which shows that the district nurses attended, besides private cases, 120 patients, and that their earnings had amounted to nearly £500. The demand for their services had been well sustained, and, with subscriptions and earnings, the institute was able to pay its way. It is proposed, with the amount remaining in hand from that subscribed to the Victoria Hall disaster (over £4000), to purchase a house and grounds at Harrogate which is now available, and to furnish and equip it as a convalescent home for children in connexion with the Sunderland Infirmary; but the matter is to be arranged, it is hoped, at an early meeting of the disaster fund.

Charitable Bequests.

It is stated that the late Mayor, Mr. Joseph Barker, J.P., of Holmefield Thornes, near Wakefield, manufacturer, left personal estate valued at £308,000, of which £15,000 is bequeathed to charitable institutions.—The late Mr. Josiah Finney of Newcastle-on-Tyne left £300 to the Royal Infirmary and £100 each to the Eye Infirmary and to the Throat and Ear Hospital of this city.

Newcastle-on-Tyne, May 18th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Aberdeen Royal Infirmary: Professor Ogston's Resignation.

THE following paragraph appeared in the *Aberdeen Evening Express* of the 12th inst.:—"Dr. Ogston, it is said, has acknowledged receipt of Mr. Littlejohn's letter on behalf of the directors of the infirmary, but the professor, while thanking the Board for their kind offer of six months' holiday, points out, I believe, though not in so many words, that he happily does not feel the need of such rest. In effect, his reply is that he cannot withdraw his resignation until the management consent to give him such facilities for his work as, in his judgment, are absolutely requisite. The profession at large, and his friends among the general public, intend, if necessary, it is said, to bring further pressure to bear on the managers to accede to the professor's requests."

Aberdeen Hospital for Sick Children.

At the monthly meeting of directors, held on May 12th, Mr. John Marnoch, M.A., M.B., C.M., Royal Infirmary, was unanimously elected house surgeon and physician for six months ensuing. The monthly report showed that there were fifty-nine patients in the wards on May 12th, that ninety-five in-patients had been treated during the month, of whom thirty-five were dismissed cured or relieved, and one died.

Aberdeen University Extension and Rearrangement of Classes.

In a circular issued to the members of the University Court and Senatus, Dr. Stephenson recommends the following arrangements to suit the alterations rendered necessary by the extension scheme:—1. That full provision be made at Marischal College for all the departments included in the medical curriculum. 2. That during the winter session the arts classes at present instituted, with the exception of natural philosophy, be held at King's College in the morning; and that natural philosophy be transferred to Marischal College, where, together with those of chemistry and geology, the classes can be conducted in the afternoon. 3. That zoology and botany be taught in the summer session at Marischal College. 4. That extra lecture-rooms be provided at Marischal College; and that the space vacated by natural philosophy in King's College be utilised for a hall, a students' common room, or an examination room.

Health of Aberdeen.

The death-rate for April was 19·43 per 1000, as compared with 23·71 in March. Dr. Matthew Hay notes that the epidemic of whooping-cough is on the wane, 191 cases having been reported, as compared with 229 in March. The slight increase in the number of cases of scarlet fever he believes to be merely temporary, and that the epidemic is dying out. There are fewer cases of typhoid fever than in any month since June last—only six reported, with no deaths. Diphtheria cases are still more numerous than usual, ten, with three deaths, having been reported. Influenza has entirely disappeared, but typhus fever has not been thoroughly eradicated, despite the vigilant efforts of the sanitary staff.

May 18th.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Royal College of Surgeons.

AN election for a member of Council took place yesterday, when, of five candidates, Mr. Arthur Benson was elected in the place of Mr. Colles, resigned. Mr. Benson is ophthalmic surgeon to St. Mark's Hospital, and was until recently an examiner in ophthalmology in the college.

Epidemic of Measles in Dublin.

Measles is still prevalent, and the deaths for the week ending May 7th were forty, the highest number recorded during the present epidemic. During the past seven weeks 176 deaths have been caused by the malady.

Child Insurance: a Bad Case.

At the City Quarter Sessions last week, Mary Delany was indicted for having ill-treated an infant aged three months. The infant was given by its mother to the prisoner to nurse, but had died, and the bill for manslaughter which the Crown had sent up was thrown out by the grand jury. The Recorder said it appeared to him that this was a case of murder, and was a terrible instance of the horrible system of insuring, not the lives of children, but insuring them for the purpose of death. It appeared from the depositions that when the prisoner was brought to the police station she stated she had the child insured for the previous three weeks, and if she was "in benefit" for six months she would get 30s., and if the child died she would get £3 if she had twelve months' benefit. He was sure, if the grand jury had these facts before them, they would not have thrown out the bill for manslaughter. He considered it a public duty to let a bad case of this kind be known, and he felt that the indictment was not at all of as grave a character as it should be. The Recorder imposed the highest sentence he could inflict—viz, two years' imprisonment, with hard labour.

Health of Dublin for March Quarter.

The births in the Dublin Registration District for the quarter ending April 2nd numbered 2483, and the deaths 3347, or 38·3, being 5·7 above the average for the March quarter. Zymotic diseases caused 477, or 318 over that of the corresponding quarter of 1891. Influenza and its complications caused 186 deaths; measles, 85; whooping-cough, 73; and diarrhœa, 28. There were 30 deaths from typhoid fever, only 1 from typhus fever, and but 3 from ill-defined fever.

The Lord Chancellor has appointed John Eustace, M.D., of Elmhurst, Glasnevin, to the Commission of the Peace.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Functions of the Supra-renal Capsules.

THE determination of the part played in the economy by the above mysterious organs is a matter of importance, especially in connexion with Addison's disease. MM. Abelous and Langlois have lately been studying the results of their partial and complete ablation in the guinea-pig. They report (Soc. de Biologie, May 7th) that the total destruction of one capsule by crushing, ligature, or cauterisation dose not bring about a fatal result. Most of the subjects maintain their normal weight, or, if they become emaciated during the few days following the operation, regain flesh quickly. In two animals out of a total of forty there was noted, however, rapid loss of flesh, followed by death. Total destruction of the two supra-renal bodies determines a fatal result after a short delay. That this effect is not caused by the mere shock of the operation is proved by the fact that the *dénouement* is the same when an interval of ten or fourteen days is allowed to elapse between the two operations. Partial destruction of the two organs, if it involve only a small portion of them, produces but an insignificant modification of nutrition. A more extensive ablation kills after a prolonged period of progressive emaciation. Mindful of the alleged virtues of the Brown-Séquard method, the experimenters essayed to replace the excised organs by the injection of their juice. The fatal result was thereby delayed to double the usual period of survival, and it was remarked that the convulsive twitchings observed in certain instances were conspicuous by their absence. The researches conducted quite recently by M. Albanese in Mosso's laboratory are confirmative of the above conclusions, which go to prove that, in some way as

Digitized by Google

yet undetermined, the supra-renal capsules are structures indispensable to the guinea-pig economy.

L'Hôpital où l'on Tue.

On the 7th inst. Paris was startled by the appearance of an article in *Le Jour* headed as above, and signed by a well-known municipal councillor. The establishment which, in the opinion of the literary ædile, merits this sinister appellation is St. Louis, and the writer proceeded to justify this contention by roundly accusing M. Péan and his *internes*, through gross neglect and non-observance of modern rules of antisepsis, of responsibility for the death of Hamonod, one of the victims of the Anarchist explosion in the Boulevard Magenta. He further formulated a grave charge against M. Camescasse, M. Péan's chief *interne*, of having unwarrantably usurped the functions of M. Ricard, the *Chirurgien de Garde*, who should have been summoned to amputate the leg of the other victim, Véry, one of whose eyes was, in addition, enucleated in the hospital. It is incontestable that, in performing a major operation, M Camescasse exceeded the strict limits of his duties. But the *interne* has ample precedents to go upon, and urgent operations are performed daily by men who, although still *in statu pupillari*, are in most cases perfectly competent to cope with such emergencies. No objection has as yet been raised against the performance by an *interne* of such a difficult operation as tracheotomy. A graver charge is that of dirtiness in the dressings in M. Péan's wards. I think I am warranted in stating that this accusation is unfounded, and that the fatal issue in the case of the two men (Véry has since succumbed to his injuries) was certainly not due to neglect. It can hardly be expected that such an acrimonious controversy as this should occur without at least one duel being fought over it. M. Camescasse, in effect, has exchanged the scalpel—a weapon which there is every reason to believe he wields very capably—for the sword, and has by this means endeavoured to convince one of his accusers—himself a medical man—of the error of his ways. The valiant *interne* succeeded in "pinking" his adversary, but it is doubtful if any other result will be forthcoming from this observance of a custom which has happily disappeared from *la vie Britannique*.

A New Academician.

At their last meeting the members of the Académie des Sciences proceeded to fill up the vacancy in the section of medicine and surgery caused by the demise of Professor Richet. There were three candidates—all surgeons—viz., Professor Guyon; Professor Lannelongue, well known as the inventor of the new sclerogenic treatment of tubercular and other affections; and Professor Duplay. Professor Guyon was elected by a small majority over M. Lannelongue.

Paris, May 18th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Ernst Brücke's Last Works.

THE celebrated physiologist, Ernst Brücke, who died not long ago, had to resign his professorship in Vienna in 1890, in accordance with the statutes of Austrian universities, which require the retirement of professors who have completed their seventy-first year. The time thus placed at his disposal was spent by him in writing two books, one entitled "Schönheit und Fehler der Menschlichen Gestalt" ("Beauty and Defects of the Human Form"), which appeared in 1891; the other, "Wie Behütet man Leben und Gesundheit seiner Kinder?" ("How can one Guard the Lives and Health of one's Children?"), which appeared after his death.

The Alvarenza Prize.

The Berlin Society of Medical Men, which bears the name of the famous physician in ordinary of Frederick William III. of Prussia, Christoph Wilhelm von Hufeland, received a large and unexpected bequest not many years ago. The Portuguese physician, Da Costa d'Alvarenza, who had enjoyed its hospitality in his youth, bequeathed it a part of his fortune, with instructions that the interest should be spent in prizes for medical work. The Alvarenza prize was offered for the first time in 1891, and the theme proposed was Influenza. The successful candidate is Dr. Ruhemann of Berlin, and his treatise has been published by Thieme of Leipsic. In obedience to the wish expressed by the Hufeland Society, he restricted himself in the main to the collecting, sifting, and arranging of the literature of the subject, treating the epidemic of 1890-91 in special detail. He refers to all the chief writings on influenza since the fourteenth century.

The Eclampsia Bacillus.

An alleged important bacteriological discovery is reported from the Pathological Institute of the University of Halle. Professor Ackermann's first assistant, Dr. Gerdes, is said to have demonstrated the presence of a bacillus in the liver, lungs, and kidneys in a severe case of eclampsia. The bacillus acts as a poison on mice and rats. It was stated to have been found in very large numbers in the above-mentioned organs.

Flagellation in Hysteria: a Judicial Inquiry.

A sensational trial took place last Monday at Kassel. The accused was Dr. Georg Moritz Wiederhold, the owner and head of the well-known establishment for the treatment of nervous diseases at Wilhelmshöhe, near that city. One of his patients was a lady of fifty-one, the wife of a retired Consul-General. In consequence of an operation she had undergone she suffered from weakness of the nerves, which had degenerated into acute hysteria. Dr. Wiederhold admitted that he had chastised her because she had become more and more uncontrollable, had acted like an obstinate child, and had indulged in crying and screaming without cause to such an extent that the other patients in the house had been excited thereby. All attempts to silence her by kindness had proved vain, and he had resorted at last to corporal chastisement. The woman had been entrusted to him as suffering from a nervous disorder, but was otherwise healthy, and her doctor had told him to treat her with rigour. When her husband visited her once he had heard him (Dr. Wiederhold) threaten her with blows. The husband had expressed his regret at that, but he (the doctor) had assumed that he approved of the treatment, if only his wife got well. He had chastised the lady three times. The first time he had given her two boxes on the ear, which she had parried. The second time, that she gave way to screaming he had gone into her room with a thin little stick, and had given her, as she lay in bed, several blows with it on the nates, which were covered by her robe. On being told that traces of the blows had been visible two months after their infliction, he said that must have been due to defective assimilation. The third time, when he chastised her in the same manner, he had used a horsewhip. He declared that he had not acted so from brutality, but only to cure the lady by physical excitation of her morbid desire to attract attention. He emphatically denied having called her "nichtswürdiges Luder" (vile bitch) and "alte Vettel" (old slut), of which he was accused. The expression "Vettel" he had indeed used, but only in admonishing her as an educated lady to give up screaming, which was not worthy of her, and the like. The examination of the husband of the ill-treated lady caused a deep sensation among the numerous audience. He was in a state of extreme excitement. He declared that he had brought the action against Dr. Wiederhold not in thirst for revenge, but in order to protect suffering mankind from the further cruelties of such a man. His wife had been so intimidated that, when he arrived to take her away, she had told him for God's sake not to speak loud, else the doctor would come and beat her. He had found her in a frightful condition; she would not be able to give evidence for a long time to come. The old servant of the family had been present only on the occasion of the boxes on the ear; on the other occasions she had been sent out by Dr. Wiederhold. The traces the blows had left were broad red desquamating stripes. He would never have consented to such treatment; on the contrary, when he had shown excitement on hearing the threat of blows, Dr. Wiederhold had said, "Do you believe I would do that? It is only a threat." His wife had told him that Dr. Wiederhold had pulled her out of bed by the hair. Dr. Wiederhold received 115 marks (shillings) a week for the patient's board and lodging, and 300 more for medical treatment (for what term is not stated). The lady's attendant gave evidence that the boxes on the ear were so administered that the lady's cheeks be-

Digitized by Google

came extremely red, and also somewhat swollen. On the other occasions she had always been sent out, but the lady had always told her afterwards. In being thrown into bed her mistress had also had her knee hurt. The doctor's general manner of treatment had been harsh. Dr. Wiederhold is a man of forty-two and of uncommon strength. Three Dresden doctors stated that they had seen the traces of considerable chastisements. Professor Tuszeck of Marburg, who gave evidence as an expert, declared that it is scientifically inadmissible to use corporal chastisement in the medical treatment of nervous patients. Of Dr. Wiederhold's establishment he had heard nothing but good. People always said: "Dr. Wiederhold is rough, but his establishment is good." The other expert, Professor Pellmann, head of the lunatic asylum at Bonn, stated that he was personally against the therapeutic application of corporal chastisement; in State establishments it was absolutely excluded. There were, however, some adherents of that method. The Public Prosecutor maintained that Dr. Wiederhold's conduct was due not to medical considerations, but to sudden anger, and denied the existence of extenuating circumstances. The counsel for the accused pleaded for acquittal, or at least extenuating circumstances, but Dr. Wiederhold was sentenced on Friday to three months' imprisonment. Extenuating circumstances were not admitted.

Miscellaneous News.

The last of Professor von Hofmann's writings—a short memoir of Peter Griess—appeared just a few days before his death. He had also finished an investigation of polymeric oils of mustard, and intended to report on it at one of the next sittings of the German Chemical Society. The place left vacant by him in the University and in the Chemical Institute will be filled during the present half by Professor Ferdinand Tiemann, who has assisted him in the Institute for years past.—Professor Krause of Halle has been appointed Head Surgeon in the City Hospital in Altona.

Berlin, May 17th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

The Climate of Canada.

To many of the readers of THE LANCET whose ideas of the climate of Canada are obtained from illustrations of our winter sports and pastimes a few items from the report of the Superintendent of Toronto Observatory may be of use as well as interest. The mean temperature during 1891 was 45·87° F., being lowest in January, 24·15°, and highest in August, 65·56°. Dividing the year into seasons, we find the mean temperature in winter 26·99, spring 53·03°, summer 63·91°, autumn 39·53°. The extremes of heat and cold were June 16th, mean temperature 77·62°, and Jan. 16th, 5·13°. Barometric pressure showed a mean height of 29·6385 inches. Of rain there fell 26·735 inches and of snow 47·8 inches, the former falling on 125 days and the latter on seventy days. Of the 4463·3 hours that the sun was above the horizon there was bright sunshine for 2065·4 hours.

Hospitals in Ontario.

From the report recently brought down to the Provincial House it appears that twenty-seven hospitals throughout Ontario received aid during 1891, being an increase of six over the previous year. The number of patients has increased from 6032 ten years ago to 10,523, the daily cost per patient during 1891 was 75·14 cents, and the proportion of State grant to the total maintenance expenditure was 32 per cent. A gratifying feature of the report is the increase in subscriptions and donations from private sources, the amount being about double that of 1890. The amount of aid to hospitals and charities was 134,992 dollars.

Registrar-General's Report for Ontario, 1890.

The report of the Registrar-General for Ontario for 1890 has just been issued. The returns show of births 47,773, a ratio of 22 per 1000 of population; the male births were 24,538, and the females 23,235, a proportion of 105·6 males to 100 females. March, January, August, and April returned the highest number; while November and February returned the lowest. In 284 cases twins were reported, and 4 of triplets. Of the total number of births, 626 were illegitimate, as against 958 in the previous year The number of marriages registered was 14,463, being a ratio of 6·9 per 1000 of population. The death-rate was at the ratio of 11·1 per 1000, the total number being 24,013; the ratio in the eleven cities was 18; 110·6 males died to every 100 females. January, August, February, and March were the most fatal months; June and November apparently the most healthy. Of infants under five years of age 69·7 deaths were returned, being 33·2 per cent. of the whole. Twenty-three deaths were returned of persons supposed to have reached 100 years and over, but the report adds that in every case satisfactory proofs were wanting as to their correctness. Phthisis, usually the principal cause of death in Ontario, gave place to pneumonia—accounted for, no doubt, by the epidemic of influenza that year—the percentage being 14·7 of the whole. Phthisis is classed second with 10·5 per cent. From the same table it appears that deaths from contagious diseases have been gradually decreasing. The last table of the report gives death by occupations, given in six classes. The average age of cultivators of the soil was 60·5 years; of mechanics, 52·1; of business men, 48·83; of professional men, 51·1; of miscellaneous occupations, 60·3; of females at work, 37·3. With a view to prevent the use of tobacco by minors a Bill was passed at the recent session of the Local House prohibiting the sale of "the weed" in any form to persons actually or apparently less than eighteen years of age Penalties are attached for the better enforcing of the Act.

During the latter part of this month a post-graduate course of two weeks' duration will be given by the Faculty of the University of Toronto. The course will be both didactic and clinical on subjects of general interest.

Toronto, May 10th.

Obituary.

PHILIP VANDERBYL, M.D.ED., M.R.C.P.L., M.R.C.S.

WE regret to have to record the death of Mr. Vanderbyl, which occurred suddenly at his London residence, 51, Porchester-terrace, Hyde Park, on the morning of Saturday, the 14th inst. Mr. Vanderbyl was fourth son of the late Hon. P. V. Vanderbyl of the Cape of Good Hope, and was born at the Cape on April 28th, 1827. He came to England in 1845, and shortly after his arrival he entered the Edinburgh University, where he secured a prize in Natural Philosophy in his first year. On taking his degree of M.D. in 1849 he obtained the highest honours and received a gold medal. Mr. Vanderbyl then visited the continental schools of medicine, and studied for two years in Paris, Vienna, and Utrecht with a view of becoming a professor in one of the medical colleges. He became President of the Royal Medical Society of Edinburgh, and within three months after his arrival in London he was appointed lecturer on anatomy and histology at the Middlesex Hospital. Becoming a Member of the Royal College of Physicians in 1855, he contributed many articles to the Transactions of the Pathological Society and to the *British and Foreign Medico-Chirurgical Review*. Mr. Vanderbyl was not, however, destined to follow out a medical career, for in 1853 he married the only child and heiress of the late Mr. James Alexander, at that time and for many years subsequently the senior partner in the well-known house of Redfern, Alexander, and Co. In the year 1885 he entered Parliament as the member for Portsmouth, but was defeated by Sir Samuel Wilson in the following year. He unsuccessfully contested Great Yarmouth in 1865, and in 1868 he was returned for Bridgewater, but was unseated on petition. He also unsuccessfully contested Winchester in 1888. By his marriage there is issue three sons and two daughters. Of the latter, the elder married Captain Clowes of the 60th Rifles, and the younger married Mr. Montrose Cloche, of 11, Queen's-gardens, Hyde Park.

JOSEPH SCHOFIELD, M.R.C.S., L.S.A.

MR. SCHOFIELD passed away at his residence, Church-street, Dunkinfield, on the 29th ult., at the age of eighty-one. After his preliminary education he selected the medical pro-

Digitized by Google

fession for his future career, and was apprenticed to the late Dr. Kay, who had a large practice at Ashton. Subsequently Mr. Schofield pursued his medical studies at Guy's and St. Thomas's Hospitals. He took the M.R.C.S. and L.S.A. qualifications, and commenced private practice in Dunkinfield, soon becoming known as a skilful accoucheur. He was a strong believer in vaccination both in theory and practice, and had, it is stated, received several Government grants for successful vaccination. About fourteen years ago he was appointed medical officer of health for Dunkinfield. As surgeon to the Ashton-under-Lyne and District Union he rendered many valuable services. The deceased leaves a widow and four children.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen have passed the First Professional Examination in Anatomy and Physiology for the diploma of Fellow:—

Cornelius A. Griffiths, M.R.C.S., of Bristol Medical School; John M. Hall, M.R.C.S., of Belfast and London Hospital; Thomas W. F. Gann, M.R.C.S., of Middlesex Hospital; Hugh Ainsworth, of Owens College; Charles M. Bryant, of Durham University; Joseph S. K. Smith, M.R.C.S., of University College, Liverpool; Edward L'Estrange Ledwich, of Peter-street Medical School, Dublin; Courtenay H. Drake, of St. Bartholomew's Hospital; George H. Hopkins, M.R.C.S., of University Colleges, London and Liverpool; Cyril H. Walker, M.R.C.S., of Cambridge University and London Hospital; Cecil M. Hewer, of St. Bartholomew's Hospital; Alan McDougall, of Owens College; St. John Stanwell, Extra-Mural School and Edinburgh University; Ernest Knight, of Owens College; Archibald W. Cuff, of St. Thomas's Hospital; Walter Roughton, M.R.C.S., of St. Bartholomew's Hospital; William S. Melsome and William S. Griffith, M.R.C.S., of Cambridge University and St. Thomas's Hospital; Frederick N. Cookson, of Middlesex Hospital; Joseph Griffiths, M.R.C.S., of Edinburgh and Cambridge Universities; Andrew H. Smith Hallidie, M.R.C.S., of London Hospital; William G. Stone, of St. Thomas's Hospital; Leonard A. Parry, of Guy's Hospital; Leonard J. Miskin and Sidney W. F. Richardson, of St. Thomas's Hospital; George H. Cowen, of London Hospital; Charles P. White, of Cambridge University and St. Bartholomew's Hospital; Francis E. Greenwood and William E. Lee, of St. Bartholomew's Hospital; Joseph H. Wilkes, M.R.C.S., of St. Bartholomew's Hospital and Cambridge University; Ernst Michels, M.R.C.S., of Würzburg, Berlin, and Kiel Universities; Robert Corfe, of St. Mary's Hospital; Frederick C. Sprawson, John S. Boden, and Arthur Bousfield, of King's College; Reginald J. Gladstone, of Aberdeen University and Middlesex Hospital; Wilfred G. Mumford, Leopold E. V. Every-Clayton, and Guy E. Manning, of Guy's Hospital; Gerald R. Baldwin, of St. George's Hospital; Alfred Banks, M.R.C.S., of St. Thomas's Hospital; Geo. L. Eastes, of Guy's Hospital; John H. Fisher, M.R.C.S., and Cuthbert S. Wallace, M.R.C.S., of St. Thomas's Hospital; Edmund B. Jones, of Charing-cross Hospital; Wilfred J. Harris, of Cambridge University and St. Mary's Hospital; Forbes Fraser, of St. Bartholomew's Hospital.

Sixty candidates were referred back to their professional studies for six months.

ROYAL UNIVERSITY OF IRELAND.—The following degrees were conferred by the Vice-Chancellor last week:—

Doctor of Medicine.—Ambrose Birmingham.

Bachelor of Medicine, Surgery, and Obstetrics.—Robert Campbell, Michael Boyle, Herbert W. Cunningham, Richard Heard, Patrick L. Aherne, Kennet B. Barnett, D. Bennett, J. F. Bennett, Henry R. Corbett, Michael Coughlan, Isaac A. Davidson, John Dodd, Wm. J. Molloy, Michael D. Sullivan, James R. Thomson.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following have obtained the Licence in Dental Surgery:—

John H. Edward. | James Wm. Smith.

NAVAL MEDICAL SERVICE.—The undermentioned gentlemen who competed at the examination held on May 2nd and following days at the Examination Hall, Victoria Embankment, for appointment as Surgeons in the Royal Navy, have been successful:—

	Marks.		Marks.
S. J. Oddie, M.B. ..	2701	G. T. Bishop	2333
H. B. Hall, M.B. ..	2668	E. F. Mortimer ..	2165
H. W. G. Green ..	2489	B. F. Parish	2161
T. E. Honey, M.D. ..	2487	F. A. Capps	2160
E. B. Pickthorn ..	2338	C. F. Warren	2157

ST. JOHN AMBULANCE ASSOCIATION.—A course of six lectures to men, on "First Aid," under the auspices of the above Association, has been given by Mr. N. Hay Forbes, L.R.C.P., M.R.C.S., of Tunbridge Wells, the average attendance being forty. At the examination forty-two candidates presented themselves, thirty-seven of whom passed.

A CENTENARIAN.—Mrs. Blanche Turner of Fornham St. Martin, near Bury St. Edmunds, has just attained her hundred and third birthday.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—The President, the Duke of Westminster, K.G., will take the chair at the annual meeting of this institution (Albany Memorial), Queen-square, Bloomsbury, at 4 o'clock on Thursday, the 26th inst., supported by Dr. J. Russell Reynolds, Sir J. Crichton Browne, Vice-presidents, and others.

KASHMIR MISSION HOSPITAL.—The report of the Kashmir Mission Hospital for 1891, by Mr. A. and Dr. E. Neve of the Church Missionary Society, shows that the work which has been carried on for many years has been vigorously prosecuted and even extended of late, the hospital, which was opened in 1875, having been almost entirely rebuilt, with considerable additions. A new feature of the work is the charge of the Maharajah's Leper Asylum, which has been entrusted to the medical missionaries by his Highness. The surgical work in the hospital continues to show most satisfactory results, for out of about 2000 major and minor operations there were only four deaths; two of these were cases of vesical calculus—a comparatively rare affection in Kashmir.

KING'S COLLEGE HOSPITAL.—The annual festival dinner was held on Saturday at the Freemasons Tavern, Great Queen-street. The Duke of Fife presided. There was a large and distinguised assembly. The chairman, in proposing the toast "Success to King's College Hospital," remarked that in such a civilisation as ours, with its great industrial populations and its more and more complex life, the hospital was an absolute necessity. In addition to their great work of relieving human suffering, they were indispensable to medical education. This institution stood in need of financial support. Its assured income was not £1000 a year. From £17,000 to £18,000 had to be raised annually, and he made an earnest appeal for liberal aid. Contributions were announced to the amount of nearly £3200.

METROPOLITAN ASYLUMS BOARD.—Sir E. S. Galsworthy presided at the usual fortnightly meeting of this board last week. He pointed out that in view of the returns showing a rapid increase of fever and also an augmentation of small-pox cases (in one day alone last week fifteen cases were admitted), it was quite clear that efforts would have to be made for the future accommodation of small-pox, and also for extra provision for fever cases. Under these circumstances a resolution was adopted that, having regard to the difficulty heretofore experienced in obtaining a site for a fever hospital, it be referred to the General Purposes Committee to consider, and, if deemed advisable, to take steps to procure the power to acquire land compulsorily, similar to the power vested in County Councils and other public bodies.

BEQUESTS AND DONATIONS TO HOSPITALS.—The Court of Common Council of London has granted 200 guineas to the Metropolitan Convalescent Institution, and 50 guineas to the "Morley House" Seaside Convalescent Home for Working Men, St. Margaret's Bay, near Dover.—The Clothworkers' Livery Company has voted £100 to the University College Hospital, London.—The Duke of Westminster has forwarded £400 to the treasurer of the London Temperance Hospital, for the benefit of the recently opened "Grosvenor Children's Ward."—The late Mrs. Oliver Haywood of Claremont, Pendleton, Manchester, bequeathed £1000 each to the Ardwick and Ancoats Hospital and St. Mary's Hospital, and £500 to the Northern Counties Hospital for Incurables.—The following legacies to the Infirmary, Worcester, were announced at the last meeting of the committee: the late Mr. Allies bequeathed £450, the late Rev. T. L. Wheeler £300, and the late Mrs. M. Wood £50.—In remembrance of the kind treatment and benefit the late Mr. Charles H. Welling received while a patient in the Bootle Hospital, and to carry out an intention which he did not live to gratify, his widow, Mrs. Welling, has announced to the secretary of the hospital that she desires to contribute £200 to the funds of the institution as a token of gratitude.

Digitized by Google

FOOTBALL CASUALTIES.—In a match played on Monday at Cochrane Park, Irvine, between the Kilwinning Engineers and the Irvine Bakers, a young man fractured his left leg. Two members of the Irish Gaelic Athletic Association, Dublin, during a game on the 8th inst., violently collided, both players sustaining injuries to their heads.

SEWERAGE WORKS, HORNSEY.—An inspector of the Local Government Board has held an inquiry into the application of the Hornsey Local Board for sanction to borrow upwards of £9000 for sewerage works, and has expressed his approval of the proposed scheme, and will report to the central authority accordingly.

THE TEACHING UNIVERSITY. — The preliminary meeting of the Royal Commission recently appointed to consider the question of a Teaching University for London will take place to-day (Saturday) Earl Cowper has returned to town, and Mr. Leybourne, who held similar office under the previous Royal Commission, has been appointed Secretary.

PROPOSED CONVALESCENT HOME, HARROGATE.—The Sunderland Calamity Fund, subscribed to nine years ago on the occasion of the Victoria Hall disaster, when 183 children lost their lives, has not hitherto been utilised for any particular purpose. A proposal at the time to erect a convalescent home for children was not carried into effect. But now the committee of the Sunderland Infirmary have taken steps by which the fund will probably be handed over to the committee, for acquiring an eligible locality for a suitable home, and Heatherdene House, Lancaster Park, has been fixed upon. The fund amounts to upwards of £4000. The amount required for the purchase money and the necessary alterations and furnishing is estimated at £3700.

THE MISSION TO DEEP-SEA FISHERMEN.—The Princess Louise, accompanied by the Marquis of Lorne, attended the annual meeting of this mission, held on Monday, at Exeter Hall. During the meeting a telegram was received from the Queen, expressing her gratification that the mission was prospering. The Princess delivered to the skippers and mates of the medical mission smacks certificates of the St. John Ambulance Association for first aid. The report (which was read) stated that the patients numbered 8130, and the missionary visits 14,278. The financial statement showed a deficit of £167. Ten mission vessels are engaged in work the maintenance of which involved an outlay of £11,000, and other items had brought up the expenditure during the year to £21,845 The chairman spoke in eulogistic terms of the efficiency and utility of the institution, and appealed to the seamen at home for more liberal support of the special hospitals the mission had established for the sick and wounded.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—The annual dinner of the members of the Pharmaceutical Society of Great Britain and their friends was held on Tuesday last at the Freemasons' Tavern. Mr. Michael Carteighe (president) was in the chair, and he was supported by Professor Armstrong, Professor Attfield, Sir G. Buchanan, Dr. J. Watt Black, Dr. J. Bell, Mr. H. J. Chaney, Dr. Cottle, Dr. Down, Professor W. D. Dunstan, Professor M. Foster, Professor Green, Dr. Farquharson, Professor Stewart, Professor Thorpe, and Sir H. Truman Wood. Dr. Farquharson replied to the toast of the Houses of Parliament, and he expressed the hope that the chairman, putting his pharmaceutical knowledge to practical advantage, might be able to tell them when a dissolution would take place. The House of Lords was so far crystallised, he thought, as to be beyond the influence of a solvent. Dr. Black replied for the medical profession, and Professor Michael Foster for the learned societies. After a few remarks from the chairman, suitably acknowledging the toast of the evening, that of the Society, the health of "Our guests" was given. About 200 members and friends sat down to dinner.

MEDICAL NOTES IN PARLIAMENT.

Galway Infirmary.

A BILL has been prepared by the Chief Secretary and the Attorney-General for Ireland for the reconstitution of the Galway Infirmary. It provides that, in lieu of the present infirmary, there shall be established a public general hospital, to be called the Galway Hospital, available for the reception of patients residing in the town and county of Galway, and managed by a board representative of the local boards of guardians. The Bill further provides that the medical staff shall consist of such surgeons and physicians of the Queen's College, Galway, or other duly qualified surgeons and physicians as may be appointed by the local Government Board, and that the hospital shall be available as a clinical school for medical students attending the Queen's College. It is specifically laid down that the hospital shall be available for any persons residing in the town or county who shall, so long as they remain in the hospital, defray the expenses of their maintenance and clothing; and for poor persons residing in the town or county who require special or surgical treatment, and the cost of whose treatment, maintenance, and clothing in the hospital is borne by the electoral divisions respectively liable.

Coroners in Boroughs Bill.

In the House of Commons, on Tuesday, the 17th inst., on the motion to go into committee on this Bill, Sir A. Rollit moved that it be an instruction to the committee that they have power to extend the provisions of the Bill to the appointment of deputies of coroners in counties, and as to the time of election. The motion was agreed to. The House then went into committee on the Bill. Sir A. Rollit moved the insertion of new clauses dealing with the appointment and powers of a deputy coroner of both a county and a borough. The clauses were agreed to, and the Bill passed through committee as amended.

Petroleum in the Suez Canal.

In reply to Mr. Aird, Mr. J. W. Lowther said the original concessions for the formation of the company and for the construction of the Suez Canal were granted to M. de Lesseps by the Viceroy of Egypt, and confirmed by the Sultan's firman. So long as the company complied with the stipulation in the concession of Jan. 5th, 1856, to treat the flags of all nations equally, Her Majesty's Government have no *locus standi* to interfere with the decisions of the company.

The Vaccination Commission.

Several questions with regard to the report of this Commission were placed on the notice paper of the House of Commons for Thursday, but owing to the absence, through illness, of Mr. Ritchie they were postponed.

The Colour Vision Committee.

In the House of Commons, on Thursday, Sir Michael Hicks-Beach, in reply to Sir Henry Roscoe, said he had received the report of the Colour Vision Committee of the Royal Society, and hoped to be able to lay it on the table in the course of a few days.

The Indian Medical Service.

Sir Guyer Hunter asked the Under-Secretary of State for India whether the advantages conferred on the Medical Staff by Royal Warrant, dated Aug. 7th, 1891, as regards rank and title, pay and allowances, had been extended to India. Would he explain why, in that country, the pay and allowances of Surgeon-Captains for the first five or six years of their service were only those of subalterns, and why the rank of Brigade-Surgeon, created in 1879, had hitherto been financially ignored so far as India was concerned; and what principle had been adopted in fixing the rate of pay of medical officers in India with reference to the rates adopted at home.—Mr. Curzon replied that the advantages of the Royal Warrant had been extended to India; it made no change in the pay and allowances of the Medical Staff. When the relative rank of the medical services was altered, and the grade of Brigade-Surgeon introduced by the Royal Warrants of 1879-80, the Secretary of State for India explicitly declined to sanction any increased charge on the revenues of India by reason of those warrants, and the present Secretary of State had no intention of departing from that decision. The rates of pay were based partly on rank and partly on length of service, but had no direct relation to the rates in force at home, nor did they vary with any variations of those rates.

THE METROPOLITAN HOSPITALS INQUIRY.

THE Select Committee of the House of Lords on the Metropolitan Hospitals met again on Monday at Westminster. Lord Sandhurst presided, and the other members present were the Earl of Kimberley, Earl Spencer, Earl Cadogan, Earl Cathcart, Lord Clifford of Chudleigh, Lord Monkswell, and Lord Zouche of Haryngworth.

Mr. Thomas Ryan, examined by the chairman, said he was chairman of a committee of secretaries of the principal hospitals appointed with a view to devising some uniform system of hospital accounts. The secretaries met and agreed to appoint a small committee of their number to determine the precise form of the accounts. This committee sat during some eight or nine months, and sent to the Hospital Sunday Fund authorities the scheme they had devised. The Hospital Sunday Fund authorities approved the scheme. A large general meeting was then held, and it too approved of what the committee had done. As a result, their system of accounts had been adopted by a considerable number of the hospitals. He should say that the principal ones had adopted it. Witness handed to their lordships three documents explaining the new system, one displaying a statement of income and expenditure, another an index of classification to guide people using the new form, and the third a synopsis of the index of classification. Witness admitted that the form was not quite that used in his own hospital—namely, St. Mary's. He imagined there were at present no accounts of London hospitals which were precisely similar. In the old form they had a heading called "Incidental expenses." This had been done away with as being a senseless sort of heading, which conveyed no meaning. Repairs had been thrown in as a subheading under "Establishment charges." They had put legacies aside and called them extraordinary income. They were included in the income and expenditure account, and in this respect the new form differed from that used in many hospitals. With the new form of accounts it would not be possible for a hospital which had received, say, £100,000 in legacies to show to the public a deficit at the end of the year. At present it was possible to have this sort of thing in some hospitals. Legacies must, under the new form, be shown as income. As a matter of fact, they would simply conform to the rule as regards any other income.

By the Chairman: Do you think this would be a more accurate guide to the public than the old form?—Witness: Speaking for the best of the hospitals, who adopted a very good form before, I do not think so, but I do think that the general public seem to want a uniform

Digitized by Google

system of accounts, which hospital experts can also see advantage in. I think it would have been a great mistake on the part of the hospitals not to regard this want of the public. But of course, if the general public expect to bring about a general likeness between unlike things, they will soon find out their mistake.

In reply to Earl Cathcart, witness said that the essential difference between the new system and the old was the introduction of this index of classification. The committee had not dealt with the out-patient departments. As a matter of fact, they had not cleared up the whole question of the accounts, because it was much more difficult to get some hospitals to join a movement of this kind than others. The Committee had only dealt with the statement of income and expenditure. They had not insisted on what the accounts should be. The question of the out-patient departments must be gone into afterwards, for it was very important.—Earl Cathcart: I wish to compliment you very much upon what you have done, because I think the form you have prepared is a very good one.

Questioned by the Chairman, witness stated that he had no knowledge of a sheet showing the daily record of meat, fish, butter, eggs, &c., consumed having been issued by the committee.

Replying to Earl Spencer, witness said they distinguished between ordinary and extraordinary repairs. A hospital might in one year have to take up the whole of the drainage system at a cost of several thousand pounds. This expenditure the committee thought should be considered as extraordinary repairs. It would not be fair to divide this expenditure into the cost per bed for the year, and therefore the committee had thrown it out in this way. He admitted that it might be more an improvement than a repair. Still the committee had to find a general title, and none better had occurred to them than what they had used.

By the Earl of Kimberley: Are repairs of a roof, for instance, ordinary repairs?—Witness: They may be so, but they cannot fairly be charged to the average per bed.—The Earl of Kimberley: Is not that in the nature of manipulating an account?—Witness: It may be so, but the manipulation is quite justifiable.—The Earl of Kimberley: It may be misleading to the public?—Witness: I do not think so. If you wish to get an accurate notion of the annual expenditure, you must do it or divide the amount over a certain number of years.—The Earl of Kimberley: I admit the difficulty is to get the average, but is it worth while arbitrarily to make this division?—Witness: I think it really has a good effect in the end.—In further examination by Lord Kimberley, witness said that the rule the committee had recommended with regard to estates was that a separate account should be kept, and the profit only brought into the hospital accounts.

In reply to the Chairman, witness said that with this system of accounts comparisons would be clear and obvious. Differences would not necessarily mean extravagance, for hospitals were differently managed. For instance, some hospitals did not supply tea and sugar.

In answer to Lord Clifford of Chudleigh, witness said that the Committee had not recommended, in the matter of repairs, that so much should be paid out of the year's income. They were anxious not to strain themselves into the position of mentors of the hospitals in other questions than accounts.

Questioned by Lord Monkswell, witness stated that it was conceivable, but not probable, that this system might lead to the stopping of repairs. At present he found hospital repairs were done in a very erratic sort of way. Everything depended on the condition of the funds.

Interrogated by the Chairman, witness said that the pay of the house carpenter, who did repairs, would appear under "Salaries and wages." Something might be said for putting it under "Repairs," but if their lordships were to go into the matter he thought they would come to the same conclusion as the committee.

The Earl of Kimberley expressed the view that the pay should be distributed so as to disclose the actual work done. It seemed to him that an account to be accurate must be accurate.—Witness: But you may carry accuracy into too great detail and become a little ridiculous.—The Earl of Kimberley: Not the least in the world. What is ridiculous is the way in which many of these accounts are kept. They are kept so loosely that nobody knows what is going on, and the looseness of the accounts is the bane of all these things.

After one or two more questions had been put and answered, Mr. Ryan was thanked for his attendance, and the Committee proceeded with the consideration of their report.

MIDWIVES' REGISTRATION COMMITTEE.

Dr. Rentoul of Liverpool was examined on Thursday before Mr. Fell Pease's Committee on Midwives' Registration. He said that by registering midwives they would practically repeal the Medical Act of 1886. By the Act of 1858 any person who was registered as a physician, surgeon, or apothecary could be placed upon a medical register. This was recognised to be an evil, because it supplied the country with partially educated practitioners. The Royal Commissioners appointed in 1882 to report upon the Medical Acts said it was a bad system, and recommended the triple qualification of medicine, surgery, and midwifery. The Medical Act of 1886 brought that into force. The Midwives Bill proposed to place the midwives upon a register giving them power to practise midwifery, and therefore it did away with the good effect of the Act of 1886 by reintroducing a partially qualified practitioner. The Bill provided only for attendance at natural labours. It did not define what a natural labour was, nor did it appoint any penalties for cases where midwives might overstep their duties. The Bill qualified the midwives to attend all cases of labour. In his opinion there ought to be training in the practice of medicine. In the Registrar-General's return for 1890 he found that 4255 women died during the year from the accidents of childbed. Of this number, 1956 died from puerperal fever. The remainder did not die from the confinement *per se*, but very likely from some accompanying disease, say, of the heart, lungs, or kidneys. If, therefore, the midwife was not educated to recognise these diseased conditions, it would be so much the worse for the lying-in woman. During 1890 he found that 15,208 infants died because they were prematurely born. The causes at work in producing premature labour in the mother were difficult to diagnose, and if the midwife had not received a medical training she could not diagnose them, far less treat the cases. The Bill also gave midwives power to treat infants during the puerperal state. Not only, therefore, must they have an education in medicine, but also in the diseases of children. It had been stated before a Select Committee that 30 per cent. of the total blindness of the country was due to infantile ophthalmia. This disease itself was frequently due to maternal gonorrhœa. Abroad the duties of the midwife were not tied down to cases of natural labour. For instance, in Belgium she was allowed to vaccinate, in Austria she was allowed to perform manual operations, in Norway and Sweden to apply forceps, and in Russia to treat diseases of infants and children. Witness called the attention of the Committee to the Medical Act lately passed in the Cape of Good Hope, where the duties of the midwives were not defined. For a considerable number of years there had been a tendency in the medical profession to dissociate the practice of midwifery from that of medicine. The nickname of "man-midwife" was applied to those who had the courage at one time to conduct confinements, and thereby raise midwifery to the level of medicine and surgery. At present even the Royal College of Surgeons refused to admit any practitioner to their Council who practised midwifery, and some years ago the Fellowship of the College of Physicians of London was refused to those men who practised midwifery. The next point Dr. Rentoul laid down was that there was not a sufficient number of maternity cases by which to train both medical students and pupil midwives. The only cases now available for the purposes of instruction were those in connexion with lying-in hospitals. The workhouses were closed against students. The same lying-in woman was sometimes visited by fourteen or fifteen different students, all anxious to record an attendance. In this way the lives of poor women were made miserable. In Liverpool a very unpleasant state of things existed. There the medical students received their instruction in midwifery, not from a medical man, but from a midwife. In his opinion, the present training of medical students in midwifery was dangerously defective. Witness was about to support this opinion with evidence, when

Mr. Rathbone, M.P., intervened, and said that the Committee could not be expected to discuss the question of medical instruction. They must confine themselves to the midwives.

Dr. Rentoul said he wished to show that they had no right to turn out the medical students in order to make room for midwives. Proceeding to another point, witness submitted that in this country it would be very difficult to have midwives properly supervised, and that the introduction of a low class of practitioners would increase criminal practices.

The Chairman: But registration will surely elevate the class of practitioners?—Dr. Rentoul: I do not think so. You suggest that 10,000 old women should be placed on the register.—The Chairman: That is only to begin with.

Dr. Rentoul, continuing, expressed the view that before passing a Bill for the registration of midwives the Legislature should pass a Bill to register stillbirths. He explained to the Committee certain malpractices of midwives. Passing from this part of his case, witness laid it down that the poor and the working classes were well provided for in existing circumstances. He referred to the work of the Poor-law authorities, charitable institutions, friendly societies, and medical men. There were 29,000 medical men in this country ready for the work. In Liverpool, he regretted to say, there were many medical men prepared to deal with midwifery cases for 7*s.* 6*d.* or 10*s.* 6*d.*, and to take their fees in instalments. In many parts of Lancashire the medical men kept a staff of collectors, who went round the districts each week gathering up the fees. Another point he wished to put to the Committee was whether, if a class of officially registered midwives were created, medical men would be able to employ such women as their legally qualified assistants in midwifery. He had put this point before the General Medical Council, and they had declined to give him an answer.

The Chairman said it was not a question for the Committee.

Dr. Rentoul assured the Committee that it deeply affected the operation of the Medical Act of 1886.

Mr. Rathbone said it would be for the General Medical Council to see to the observance of that Act.

Dr. Rentoul, examined by Dr. Farquharson, M.P., expressed the view that poor people derived more assistance from their neighbours than from midwives. He found patients ready to pay him 30*s.* and two guineas in order to escape from midwives. If people desired women practitioners they were well supplied at present by women doctors.

METROPOLITAN ASYLUMS BOARD.

Return of Patients remaining in the several Fever Hospitals of the Board at Midnight on May 17th, 1892.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ANDREW, HENRY, M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the Devon and Exeter Hospital, vice R. Martyn.

ARCHER, A. M., M.D., L.M. Dub., has been appointed Medical Officer of the Workhouse, Chester Union.

ATKINS, J. F., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Medical Officer to the Workhouse Infirmary, Birmingham.

BARNETT, LAWRENCE, M.D. Lond., M.R.C.S., has been appointed Honorary Physician to the Kilburn, Maida-vale, and St. John's Wood General Dispensary.

BEAN, CHAS. E., L.R.C.P. Lond., M.R.C.S., has been appointed Analyst for the Plymouth County Borough, vice Oxland, resigned.

BERRY, A. E., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Assistant Medical Officer of the Crumpsall Workhouse, Township of Manchester.

BLAKE, S. R., M.R.C.S., L.R.C.P. Lond., has been appointed Senior House Surgeon to the West Ham Hospital.

BURTON, W. E., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Frodsham Sanitary District of the Runcorn Union.

CONWAY, AUBERT, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Kingswinford (No. 2) Sanitary District of the Stourbridge Union.

FISHER, T. E., L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon to the West Norfolk and Lynn Hospital, Lynn.

FLETCHER, F. J., L.S.A., has been appointed Medical Officer for the Fourth Sanitary District of the Bourn Union.

GODSON, J. E., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Medical Officer to the Workhouse Infirmary, Birmingham.

HELPS, G. C., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer for the Wells Sanitary District of the Frome Union.

HILLIER, R. J., M.R.C.S., L.R.C.P. Lond., has been appointed Junior House Surgeon to the West Ham Hospital.

LEES, C. F., M.B., C.M. Edin., has been appointed Medical Officer for the Infirmary of the Salford Union.

MARNOCH, JOHN, M.B., C.M. Aberd., has been appointed House Physician and Surgeon to the Sick Children's Hospital, Aberdeen.

PATTERSON, WM., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Seventh Sanitary District of the Oldham Union.

SMITH, HENRY, M.B., C.M. Dur., has been appointed Medical Officer for the Workhouse of the Durham Union.

SMITH, H. H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Lye and Wollescote Sanitary District of the Stourbridge Union.

THOMPSON, E. T., L.K.Q.C.P., L.R.C.S. Irel., has been appointed Medical Officer for the Dunstable Sanitary District of the Luton Union.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

ADDENBROOKE'S HOSPITAL, Cambridge.—Resident House Surgeon. Salary £65 per annum, with board, lodging, and washing in the hospital.

BOROUGH OF CHELTENHAM.—Medical Officer of Health for three years. Salary £500 per annum. (Apply to the Town Clerk, Cheltenham.)

BRADFORD INFIRMARY.—Dispensary Surgeon. Salary £100 per annum, with board and residence.

BURTON MEDICAL ASSOCIATION.—Junior qualified Assistant. Salary £150 (out-door). (Apply to Mr. Blant, Ebenezer, Shobnall-road, Burton-on-Trent.)

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical Assistants.

CLAYTON HOSPITAL AND WAKEFIELD DISPENSARY, Wakefield.—Junior House Surgeon. Honorarium £25 per annum, with board, lodging, and washing.

DENTAL HOSPITAL OF LONDON, Leicester-square.—Dental Surgeon.

DEVON AND EXETER HOSPITAL, Exeter.—Assistant House Surgeon. Salary £40 per annum, with board and lodging, not including alcoholic liquors and aerated waters.

GENERAL HOSPITAL, Birmingham.—Assistant Physician for three years. Honorarium £100 per annum.

GROSVENOR HOSPITAL FOR WOMEN AND CHILDREN, Vincent-square, S.W.—Chloroformist.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—Resident House Physician for one year. Salary £60 per annum, with board and residence in the hospital.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—Assistant House Surgeon (non-resident) for one year. Salary £50.

HOSPITAL FOR WOMEN (LONDON SCHOOL OF GYNÆCOLOGY), Soho-square, W.—Clinical Assistants.

LEEDS UNION.—Assistant Medical Officer and Dispenser for the Workhouse, Schools, and Infirmary in Beckett-street, Leeds. Salary £100 per annum, with board, washing, apartments, and attendance. (Apply to the Clerk, Union Offices, East Parade, Leeds.)

LIVERPOOL ROYAL INFIRMARY.—Assistant Honorary Physician and Two Assistant Honorary Surgeons.

NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL.—Assistant Ophthalmic Surgeon. (Apply to the Secretary, Hartshill, Stoke-on-Trent.)

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Resident Medical Officer for four months. Salary at the rate of £60 per annum, with board and residence.

ST. BARTHOLOMEW'S HOSPITAL.—Surgeon.

SALOP INFIRMARY, Shrewsbury.—House Surgeon. Salary £100 per annum, with board and residence.

VICTORIA HOSPITAL FOR CHILDREN, Queen's-road, Chelsea, S.W.—Dental Surgeon.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—Resident Assistant for six months. Board, lodging, and washing provided.

WORCESTER GENERAL INFIRMARY.—Assistant to the House Surgeon and as Dispenser (unmarried), for one year. Salary £70 per annum, with board, residence, and washing.

Births, Marriages, and Deaths.

BIRTHS.

ELIOT.—On May 10th, at East Park-terrace, Southampton, the wife of Dr. E. F. Eliot, of a daughter.

FOX.—On May 15th, at Strathpeffer Spa, N.B., Katharine, the wife of Dr. Fortescue Fox, of a son.

GROSVENOR.—On May 9th, the wife of A. Augustus Grosvenor, B.A., M.R.C.S., of a daughter.

HANDFIELD-JONES.—On May 12th, at East-hill, Wandsworth, S.W., the wife of C. R. Handfield-Jones, M.R.C.S., L.R.C.P., of a son.

KIRKHAM.—On May 7th, the wife of F. W. Kirkham, M.D., L.R.C.P., of a son.

MOORE.—On May 11th, at Redcroft, Maidenhead, the wife of G. E. Moore, M.B., of a son.

MARRIAGES.

OAKLEY—CRIPPS.—On April 26th, at the Parish Church, Cirencester, by the Ven. Archdeacon Hayward, assisted by the Rev. Alan Cornwall, Vicar of Coleford, Adam R. H. Oakley, L.R.C.P. Edin., of Horuchurch, Essex, second surviving son of Sir Henry Oakley, of Chester-terrace, Regent's-park, N.W., to Ellen Judith, second daughter of the late Edward Cripps, M.R.C.S., of Cirencester.

ROBERTS—SCOTT.—On May 17th, at All Saints', Eastbourne, Charles Gordon Roberts, M.A., M.B. Cantab., youngest son of Bransby Roberts, of Eastbourne, M.D., to Janet Bogle (Nettie), eldest daughter of the late James G. T. Scott, C.E., of Truro House, Burlington-place, Eastbourne.

SKRIMSHIRE—GROOMES.—On May 10th, at the Parish Church, Shalford, Essex, the Rev. Arthur J. Skrimshire, M.D., Rector of Hadleigh, Essex, eldest surviving son of the late Fenwick Skrimshire, M.D., of Paston Hall, Peterborough, to Agnes Maria, only daughter of the late Rev. John Groomes, M.A., Vicar of Shalford.

DEATHS.

EADY.—On May 13th, at Chertsey, Surrey, Geo. John Eady, Surgeon, in his 76th year.

HENDRY.—On May 13th, at Cullen, Banffshire, Alexander Hendry, M.B., C.M. Edin.

NICHOLSON.—On May 16th, suddenly, at Woodlands, Harefield, Middlesex, John Frederick Nicholson, F.R.C.S., aged 75.

NUNN.—On May 10th, at his residence, The Mount, Higher Broughton, Manchester, Dr. Nunn, late of Lyndhurst, Hants, aged 47.

PATERSON.—On May 15th, at Grosvenor-terrace, Glasgow, Joshua Paterson, M.D., aged 78.

QUICKE.—On May 12th, at Albert House, Bradford-street, Manchester, Frances Cole ("Fanny"), wife of W. J. Quicke, M.R.C.S. &c.

RANDALL.—On May 14th, suddenly, at 204, Adelaide-road, South Hampstead, John Randall, M.D. Lond., F.R.C.S., &c., aged 74.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Digitized by Google

Medical Diary for the ensuing Week.

Monday, May 23.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Tuesday, Wednesday, Friday, and Saturday at the same hour.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations daily at 10 A.M.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.

UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.

LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital: 1 P.M., Mr. Wm. Lang: Conjunctival Affections.—Great Northern Central Hospital: 8 P.M., Dr. Galloway: Gastro intestinal Tract.—Parkes Museum (Margaret-st., W.): 4 P.M., Dr. A. Wynter Blyth: Construction and Ventilation of Dwelling Houses.

ROYAL COLLEGE OF SURGEONS.—4 P.M. Dr. J. Rose Bradford: The Physiology of the Vaso-motor System.

NATIONAL ORTHOPÆDIC HOSPITAL (Great Portland-street, W.).—5 P.M. Mr. E. Muirhead Little: Deformities of the Head and Trunk, including Diseases of the Spine and Wry Neck.

Tuesday, May 24.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.; Fridays and Saturdays at the same hour.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same day, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Professor R. C. Jebb: Some Aspects of Greek Poetry.

LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars: 4 P.M., Mr. Jonathan Hutchinson: Eczematous Dermatitis.—Bethlem Hospital: 2 P.M., Dr. H. Corner: Stupor and Dementia.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Dr. A. E. Garrod: The Changes in the Blood in the course of Rheumatic Attacks.—Mr. Hugh Lane: Further Observations in reference to the Distinctions to be drawn between Rheumatoid Arthritis and Rheumatic Arthritis.

Wednesday, May 25.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1.30 P.M.; Saturdays, 2 P.M. Obstetrical Operations, Thursdays, 2 P.M.

CHARING-CROSS HOSTITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.30 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.

LONDON POST-GRADUATE COURSE.—Hospital for Consumption, Brompton: 4 P.M., Mr. R. J. Godlee: Surgical Treatment of Empyema.—Royal London Ophthalmic Hospital: 8 P.M., Mr. J. B. Lawford: Toxic Amblyopia.

ROYAL COLLEGE OF SURGEONS.—4 P.M. Dr. J. Rose Bradford: The Physiology of the Vaso-motor System.

Thursday, May 26.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.

ROYAL INSTITUTION.—3 P.M. Mr. R. G. Moulton: Faust.

LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Great Ormond-st.: 4 P.M., Dr. Hadden: Selected Cases from the Out-patient Department.—National Hospital for the Paralysed and Epileptic: 2 P.M., Dr. Ormerod: Hemiplegia.—London Throat Hospital, Gt. Portland-st.: 3 P.M., Mr. W. R. H. Stewart: Causation in Ear Disease.

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square).—8.30 P.M. Dr. Fancourt Barnes: Ovariotomy during Pregnancy. Specimens:—Dr. Wm. Travers: Dermoid Cyst.—Dr. J. Inglis Parsons: Stone from the Urethra.

Friday, May 27.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

LONDON POST-GRADUATE COURSE.—Hospital for Consumption, Brompton: 4 P.M., Mr. R. J. Godlee: Surgical Treatment of Pulmonary Cavities.—Bacteriological Laboratory, King's College: 11 A.M. to 1 P.M., Professor Crookshank: Tuberculosis (Examination of Sputum). Charing-cross Medical School: 8 P.M., Dr. Potter: Pessaries, their Object and Use.

ROYAL COLLEGE OF SURGEONS.—4 P.M. Dr. J. Rose Bradford: The Physiology of a Vaso-motor System.

CLINICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Nunn: A case of Cubitus Valgus and Cubitus Varus arising from Fracture at the Elbow-joint.—Mr. Frederick Treves: A case of Sarcoma of the Buttock treated by Ligature of the Internal Iliac Artery.—Mr. Clutton: A case of Gastrostomy for Stricture of the Œsophagus at the age of four; eventual restoration of the normal passage.—Dr. Douglas Drew (introduced by Dr. Ringer): A case of Leucocythæmia treated with Arsenic. 9 30 P.M. Annual Meeting.

ROYAL INSTITUTION.—9 P.M. Sir J. Crichton-Browne: Emotional Expression.

Saturday, May 28.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

LONDON POST-GRADUATE COURSE.—Bethlem Hospital: 11 A.M., Dr. H. Corner: Climacteric and Senile Insanity.

ROYAL INSTITUTION.—3 P.M. Professor H. Marshall Ward: Some Modern Discoveries in Agriculture and Forest Botany.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the Journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

"A NEW USE OF THE TITLE M.B."

THE following is another instance of the audacious use of the title M.B. to which we referred in our last issue. The correspondent who sends it to us wonders that those representing the profession do not take steps to prevent this. Our reply is that the M.B. is not attached to any particular institution which can feel itself aggrieved. Meanwhile the public falls between two stools:—

> "D. Wilkinson, M.B., Chapel-street, Ripley, Derby, removes Tumours, Cancers, and Abscesses, without cutting; also removes the Germs of Consumption, even when they are given up."

An Anxious Inquirer.—The authority would have to be more than presumably trustworthy to induce us to believe that the converse o Goldsmith's lines would hold good—

> "The man got better of the bite,
> The dog it was that died."

All patients bitten by mad dogs do not, of course, suffer from hydrophobia; but, so far as we know, there are, at present, no well-authenticated instances recorded of true hydrophobia resulting from the bite of a dog that was not affected with rabies. Of course, there are cases of death after the bite of a dog, from shock and fright, the effects of nervous excitement; but these cannot be reckoned as cases of hydrophobia in the recognised sense of the term.

Country Surgeon will perhaps be able to obtain the information he desires from the Secretary of the Brussels Graduates' Association, Florence House, Ealing.

POST NON PROPTER!

To the Editors of THE LANCET.

SIRS,—As a specimen of anti-vaccinationist "argument" the following may, I think, be found amusing. A young woman brought her baby to be vaccinated this evening. "It's a shame," said she, "that we should have to do it." "But surely," I replied, "you would rather have the child vaccinated than let him get small pox." "Oh, doctor," was the answer, "small-pox is out of date now."

I am, Sirs, yours truly,

May, 1892. GELASMA.

Digitized by Google

SHAFTS AT THE PROFESSION.

MANY are the witty tales which have been told of, and by, medical men. Sir John Hill, for instance, a medical man of great renown in the last century, formed, by reason of his eccentric habits, a fertile source of inspiration for many of the wits of the period. He rarely failed, however, to turn the tables on his assailants. He was a voluminous writer, his chief work being a "System of Botany" in twenty volumes. Mr. J. Lovett de Wolfe reminds us of the "Juntos" (supposed to be friends of Garrick), who wrote witty passages to the public prints against the old doctor. Alluding to his botanical researches, and to certain lines which he had written, they wrote:—

"Thou essence of dock, valerian, and sage,
At once the disgrace and pest of the age;
The worst that we wish thee for all thy sad crimes
Is to take thy own physic and read thy own rhymes."
The Junto.

The next appeared in answer to "The Junto," as follows:—

"Their wish in form must be reverst,
To suit the doctor's crimes;
For he who takes his physic first
Will never read his rhymes."—*Another Junto.*

But the shrewd doctor was equal to the occasion. He replied by sending to one of the papers the following lines:—

"Ye desperate Junto, ye great, or ye small,
Who con bat dukes, doctors, the devil and all,
Whether gentlemen scribblers, or poets in jail,
Your impertinent curses will never prevail;
I'll take neither sage, dock, valerian, nor honey,
Do *you* take the physic, and *I'll* take the money."

Kentigern.—We have not seen any announcement of a second volume of Hillairet et Gaucher's "Traité des Maladies de la Peau." Part IV. of Leloir and Vidal will doubtless be published in the course of this year, as hitherto one part a year has been published.

Dr. J. Cartwright Reed (Herschel, Cape Colony) is thanked for his communications, which would scarcely be of sufficient interest for publication at the present time, as they refer to occurrences that took place so long ago.

FLOATING SPLEEN.

To the Editors of THE LANCET.

SIRS,—During an unusually long professional life I have had the opportunity of seeing many instances of that anatomical peculiarity, the "floating kidney." Discussing the matter lately with a medical friend, I came to the impression that a case he related to me as being, he supposed, one of this anomaly, was perhaps a case of "floating spleen." In all the cases of floating kidney which I have met with I have always detected the form and size of the adult kidney, and besides, not seldom, have found that the mass has disappeared on the patient assuming the recumbent position, until I had made an upward pressure at the loin; but in the case related by my friend the tumour was always to be felt, though not always in the same spot, and, moreover, always in the left pelvic region. He stated that its form was not that of the kidney—that is, was of a somewhat larger size, and more like the shape of the spleen. That the matter is of some moment I need scarcely say, and therefore I am induced to ask your many correspondents whether their attention has been drawn to the subject. I have myself only succeeded in finding one reference to it—i.e., by a Dr. Gustav Klein, who found, at a necropsy, a "floating spleen" in the pelvis. (*Vide* p. E. 16, the "Annual of the Medical Sciences," vol. ii., 1890.)—Yours truly,

Birkenhead, May 16th, 1892. CHAS. H. HIGGINS, M.D.

A PRACTICAL SUGGESTION FOR THE IMPROVEMENT OF THE PRESENT HOSPITAL SYSTEM.

WE have received from a correspondent a communication which is interesting, but not practical. It is entirely unpractical, and contrary to the laws under which the Medical Council acts, according to the spirit of which all persons on the Register are equally "qualified," and in the letter of which there is nothing to sanction the Council undertaking such extraordinary functions. The hospitals of England at least must either be conducted as voluntary institutions, or undergo an entire revolution in their constitution and in the basis of their support.

H P.—We would suggest to our correspondent to make an official application to the Colonial Office, setting forth his requirements and professional qualifications, and asking for information as to any vacancies.

A CORRECTION.

To the Editors of THE LANCET.

SIRS,—Please allow me to contradict the statement which appeared in THE LANCET that Brigade-Surgeon Maunsell died of yellow fever at Up Park Camp, Jamaica. As one of the medical men who attended the late Brigade-Surgeon Maunsell from Nov. 17th to the day of his death, which occurred on Dec. 5th, 1891, I am in a position to state that his disease was not yellow fever. I am, Sirs, yours obediently,

JASPER CARGILL, M.D.

Monaltrie, St. Andrew, Jamaica, May 2nd, 1892.

OBSTETRIC AMENITIES.

Mr. B. M. Bond.—There is nothing which tries the good temper of medical men more than the call to attend an obstetric case from a brother practitioner, perhaps in the night or at great personal inconvenience. Such demands should not often arise, but they will occasionally occur. And every right-hearted practitioner will do as our correspondent did. The gentleman for whom he acted should at the very first opportunity show his appreciation of the act of kindness. Our correspondent assumes that his neighbour neglected to do this because he did not do so on first visiting the patient. This seems to us somewhat hasty judgment. At any rate, we should require to know all the facts and all the engagements of Mr. —— before we could decide. Be this as it may, it would have been better for Mr. Bond to have given a little more time to Mr. —— before writing him a "polite note" and claiming a fee. A little time solves many questions of this sort. With this qualification, we entirely approve Mr. Bond's conduct in the matter, and regret that on the other side the correspondence was not quite couched in terms which did justice to him and to his prompt action in the case. There should be no difficulty in putting this matter right between neighbours.

Dubitans.—The question is one which could be best answered by the medical attendant, who knows the time of onset of the inflammation with reference to the use of the injection or of the unusual exertion. The complication is very common where no injection is used.

"A MUSEUM OF CURIOSITIES."

To the Editors of THE LANCET.

SIRS,—In answer to your correspondent of the 14th inst., it is hardly necessary to point out that the case recorded should not be classed as one of true hermaphroditism. The mere fact that the testicles were present, coupled with hypospadias and the absence of vaginal orifice, is sufficient evidence that the case was only one of arrested development in the male embryo. On the other hand, the presence of a depressed fissure of the sacral spines, which is of great interest, seems hardly to have engaged the attention of your correspondent. There is good reason for assuming that this condition represents an obliterated state of the neurenteric canal of the embryo; and, indeed, a few similar cases have already been recorded. It also would have added interest to the case if auscultation over the præcordium had been attempted, with a view to determining the presence or absence of cardiac deformity.

I am, Sirs, yours faithfully,

May 17th, 1892. EMBRYOLOGIST.

"THE TITLE OF DOCTOR."

To the Editors of THE LANCET.

SIRS,—Will you allow me to correct the statement of your correspondent "M.B. Lond." in his letter dated May 9th, 1892, in which he says that the Scotch, Irish, and English universities (except London University) grant a M.D. degree to their M.B. graduates on payment of a fee and the production of a thesis? In the Royal University of Ireland the M.D. degree is only granted to its M.B. graduates after passing an examination which extends over three days, and consists of two written papers, two clinical, oral, and practical pathological examinations; and this examination was until recently accepted for promotion in the army in place of the Fellowship of a College. The graduates of the Royal University, Ireland, consider themselves—and justly—on equal standing with the graduates of London University.

I am, Sirs, yours faithfully,

May 15th, 1892. M.B., R.U.I.

"STRICTURE OF THE URETHRA."

To the Editors of THE LANCET.

SIRS,—There is a mistake in my paper on Stricture in THE LANCET of April 9th, 1892, which destroys its sense. I did not say that "under no circumstances whatever is *external* urethrotomy a justifiable operation," but that under no circumstances whatever is *internal* urethrotomy a justifiable operation. If a surgeon can pass instruments, he can dilate all organic strictures. If he cannot, then he can perform external urethrotomy; and external urethrotomy is also very often the only operation advisable in traumatic strictures.

I am, Sirs, your obedient servant,

EDWARD LAWRIE,
Surgeon-Lieutenant-Colonel.

The Residency, Hyderabad, April 28th, 1892.

THE REPORT ON COLOUR VISION.

To the Editors of THE LANCET.

SIRS,—Will you kindly state in THE LANCET that a mistake has occurred in the Report of the Colour Vision Committee of the Royal Society? It is there stated that two colour-blind persons were passed by me. Both these men were rejected by me, and no colour-blind person escaped detection by either of my tests. Capt. Abney says that the unfortunate error was due to my using a nomenclature different from that generally adopted, and that he will correct it.

I am, Sirs, faithfully yours,

F. W. EDRIDGE-GREEN, M.D.

Willesden-green, N.W., May 18th, 1892.

MODERN PHARMACY.

KEPLER SOLUTION OF COD LIVER OIL.

THIS is, according to the BRITISH MEDICAL JOURNAL, "an ideal form for the administration of fat." It is a well-known fact that when fatty material is ingested *en masse* it to a very large extent escapes emulsification during its passage through the alimentary canal. If, on the other hand, it is mixed intimately with other foods, the disintegration process has already been accomplished and the fat is readily acted upon by the secretion of the pancreas, succus entericus, and the bile. Cod Liver Oil is no exception to this rule, and, according to recent investigations, a very large proportion of the oil taken by a selected number of patients was voided unchanged in the fæces; whereas oil given in a condition similar to the Kepler Solution of Cod Liver Oil was perfectly absorbed, and merely a trace of fat only was discovered unchanged. The Kepler Solution contains a very large percentage of Cod Liver Oil, the remaining part of it consisting of a rich and nutritious Extract of Malt. Everything considered, this preparation is one of the most perfect foods and resuscitating agents it is possible to prepare. THE LANCET reports: "It has hardly any of the taste of the oil. Many can take it who could not take the oil." The BRITISH MEDICAL JOURNAL reports: "The taste of the oil is agreeably disguised, its nutritive qualities are greatly increased, and it is rendered easy of digestion." Again, THE LANCET reports: "It is the best known and most largely used." The MEDICAL PRESS AND CIRCULAR: "The most palatable and easily digested."

The Kepler Solution of Cod Liver Oil is supplied to the Medical Profession in ¾-lb. and 1½-lb. bottles, at 1/8 and 3/- each; retail, 2/6 and 4/-.

KEPLER EXTRACT OF MALT.

This preparation contains all the essential principles of Barley Malt in an agreeable and concentrated form. It is especially rich in diastase—the digestive principle which converts starch into dextrines and maltose. Opinions vary as to whether the immense utility of Extract of Malt depends more upon the diastase than the nutritive principles contained in it. In many debilitated conditions, however, it is generally conceded that the nutritive principles of dextrines, maltose, and natural phosphates are absolutely necessary. A tablespoonful of the Malt Extract under such circumstances is equivalent to a large percentage of farinaceous foods. Undoubtedly diastase, however, is very valuable in converting starchy material into soluble conditions suitable for ready assimilation.

Kepler Extract of Malt is an excellent sweetening agent for gruels, rice puddings, &c. It is an invaluable adjunct to peptonised milk and to foods for infants. The Malt Extract prevents the milk curdling in large clots, and therefore assists materially in the digestion of the food.

VERDICT.

THE LANCET reports: "The Kepler Extract of Malt is the best."

The MEDICAL TIMES AND GAZETTE: "By far the best."

The MEDICAL PRESS: "Delicious to the taste."

The Kepler Extract of Malt is supplied in ¾ lb. and 1½-lb. bottles, at 1/8 and 3/- each; retail, 2/6 and 4/-.

KEPLER ESSENCE OF MALT.

We have recently introduced a new food agent and aid to the digestion of farinaceous substances under the above name. This preparation is manufactured by a modification of the KEPLER process for making the well-known **Kepler Extract of Malt.**

The Kepler Essence of Malt contains a large amount of **Diastase** and natural mineral phosphates and a considerable amount of tissue-forming substances. *The immense superiority of this preparation over ale and stout* is at once apparent when the process of manufacture is considered in detail. In making ale and stout the carbohydrates (so valuable as nutrient material) and the diastase (a most important principle of Malt, being of special service in errors of nutrition accompanied by digestive derangement) are sacrificed for the production of alcohol; whereas *in the Kepler Essence of Malt these are carefully preserved intact.* This Essence is therefore an ideal aid to digestion and nutrient agent. **A wineglassful of the Kepler Essence of Malt contains more elements of nutrition than a pint of the finest alimental stout.**

The flavour of the Essence of Malt is delicious. It is admirable as a table beverage when diluted with aerated water, and as an addition to milk for infant and invalid dieting; for it sweetens it and facilitates its prompt and perfect digestion. The Essence may be taken in coffee, gruel, aerated or plain water, wine, or mixed with any farinaceous pudding. As an addition to the food for young children its value cannot be over-estimated. It increases the value of all farinaceous food and prevents the starch in such food, and large clots of curd in milk diet, overtaxing the power of the digestive functions.

For Lactating Women the Essence of Malt (Kepler) contains many desirable properties; it quickly increases the flow and enriches the quality of the milk. It is serviceable as a laxative for young children, especially when constipation depends upon the defective digestion of starch. As a food beverage, it cannot fail to be productive of the highest benefit, either in **acute disease** or during **convalescence**; in fact, wherever there is defective nutrition, the Kepler Essence of Malt is useful as a nutritive food.

As a Linctus, the Essence of Malt food, swallowed slowly, in the troublesome, dry, laryngeal cough, and the hacking cough of puberty or consumption, is pleasantly grateful and soothing, aids digestion, and builds up the tissues.

The Kepler Essence of Malt is supplied to the profession in champagne pints at 1/2 each. Retail, 1/6 each.

MALTO RICINE (Kepler).

Castor Oil has long been considered a valuable laxative, especially for parturient women and children, and although much dreaded on account of its nauseating character, was nevertheless most effective in producing a comfortable relaxation of the bowels. Taking as our guide the Kepler Solution of Cod Liver Oil, wherein the oil is rendered palatable through being dissolved in Extract of Malt, we performed similar experiments with Castor Oil, and in the Malto Ricine the repugnant odour and flavour of the oil are thoroughly hidden; moreover, the aperient action is enhanced by the laxative effect of the Extract of Malt. It is palatable, and therefore readily taken by children or fastidious patients. The demulcent, mild, aperient, and soothing properties of the Malt Extract render it especially adapted for mixing with and masking the disagreeable properties of Castor Oil, thus rendering it agreeable to those unable to take the clear oil.

Malto Ricine is more reliable in effect, since the whole of the oil passes into the intestinal canal and readily excites peristalsis. It never excites nausea or vomiting.

Malto Ricine is supplied to the Medical Profession in ¾ lb. bottles at 1/8 each. Retail, 2/6.

BURROUGHS, WELLCOME, & CO., SNOW HILL BUILDINGS, LONDON, E.C.

Samples of these Preparations supplied to Medical Men free on request.

DESIDERATA Maltine REALISED.

THAT Malt Extract is a food of great value, and that the action of diastase is of peculiar service in many lines of treatment, are facts well known by the Profession. What is naturally not so patent to the physician are the chemical problems involved in its manufacture, and the varying success with which these are solved in the different articles that compete for his favour.

It will be conceded that the first essential of malt extract is diastasic activity, and it is just here that they nearly all fail ignominiously.

Nor is this surprising. The retention of the ferment diastase during the process of manufacture is a most difficult and delicate operation, demanding the greatest care and elaborate appliances. The bulk of the extracts that flood the market appear to be recommended solely for their cheapness, and are practically innocent of any digestive ferment. Comprehensive analyses have demonstrated the fact that only two malt extracts had any decided action on starch, and "Maltine" contained about four times as much diastase as any other. These facts are explained by the ordinary method of preparation, in which the extracts are heated to the boiling point, with consequent coagulation and deposition of the diastase and albuminoids. Whether it is worth while prescribing malt extracts that are devoid of the principle for which malt extract is chiefly valued, is a *question* that does not require much discussion. For most medical men it is settled by taking advantage of the *proved* diastasic superiority of "Maltine," which is now usually specified in prescriptions. By means of the vacuum process, original with this Company, the extract is evaporated at a very low temperature, and thus the diastase of the malted grains is conserved and the maximum digestive activity attained.

Besides being a most powerful aid to the digestion of farinaceous foods, "Maltine" affords a store of digestible nutriment in a concentrated form. The process of manufacture provides for the retention of the albuminoids of the grains, which in the other extracts are destroyed by the excessive heat employed. Maltine further contains a considerable amount of the digested carbo-hydrates (dextrine and maltose), and is especially rich in the natural phosphates of the grains, vitalised, as they have been, by the process of germination.

We need but briefly outline the uses of this standard preparation. In infant dietetics it has achieved great success; the diastase takes the place of the *ptyalin* absent in young infants, and so effects the digestion of the food. Dr. Milner Fothergill expressed an opinion, to which many doctors will subscribe, in the remark that "if a certain portion of baked flour were added to plain milk, and some Maltine mixed with it before it is placed on the nursery table, we should hear much less of infantile indigestion and mal-nutrition."

The use of Maltine has been found very beneficial in the case of *Nursing* Mothers; it increases the supply and improves the quality of the milk; its laxative tendency is a feature of value, while its properties as a *Food* render it far superior in this connexion to ale and stout. In Rickets and Phthisis Maltine has been proved to be of great service, and generally it may be said that in convalescence and whenever the functions of nutrition are at a low ebb, the happiest results are noticed from the use of this digestive nutrient.

Maltine should be added to the various forms of farinaceous food, or if given after the meal should be taken immediately afterwards. Mixed with soda or lemonade it makes a palatable strengthening beverage.

Maltine is of a light amber colour, convenient consistence, and possesses a delicious flavour, and thus differs materially from the dense unpalatable extracts, to which so much repugnance is evinced by patients.

The word "MALTINE" is our registered Trade Mark. In prescribing Malt Extract, kindly specify—"THE MALTINE MANUFACTURING CO."

WE SHALL BE PLEASED TO SEND SPECIMENS FREE OF CHARGE TO MEDICAL MEN. SPECIAL TERMS TO THE PROFESSION AND HOSPITALS.

THE MALTINE MANUFACTURING COMPANY, Limited,
24 & 25, HART STREET, BLOOMSBURY, LONDON, W.C.

ABSTRACT OF A

Lecture

ON

AURAL POLYPI.

Delivered at Charing Cross Hospital on Feb. 17th,

BY A. MARMADUKE SHEILD, M.B., F.R.C.S.

THE word "polypus" is of great antiquity in medicine; for this reason we still retain it. The name is by no means a good one, because the growths to which it is applied have usually a single stalk, are pedunculated, and quite devoid of "many feet" or protruding processes, like a fresh-water polyp. It may be generally stated that any growth of a canal, or cavity of the body, which becomes pedunculated, and attached to the surface from which it springs by a stalk, is called a polypus. Thus we have polypi of the nose, of the rectum, of the bladder, and of the uterus. This word, also, does not give us any idea of the exact structure of the growth, which, indeed, may be diverse in nature. These tumours, growing as they do without infiltration of the tissue from which they arise, are not malignant; but this rule is not devoid of serious exceptions, as we find if we study the literature of polypoid growths, in various situations. Much mystery has been attached to the consideration of polypi of the ear, as though they were of a quite exceptional nature. The pathology of them is a matter of no extraordinary difficulty, but the treatment is always complicated, and often not unattended with risk to life. I believe that the majority of aural polypi grow from within the tympanic cavity, and have their origin in the constant irritation of a focus of necrosis. The carious bone may be on the superficial aspect of the tympanic walls or it may be in the mastoid or other part of the temporal bone; the polypus then springing about the orifice of the sinus by which the disease communicates with the tympanic cavity. It must early be recognised that these growths have their origin in perforative otorrhœa, neglected and of long standing. They protrude through the aperture in the drum, and are moulded as they grow by the walls of the canal into into polypoid form. Aural polypus would not be so common a disease if the treatment of otorrhœa was commenced early and persistently and carefully carried out. Polypi also originate from the walls of the auditory canal; here they may be caused by a "spot" of caries. They may originate round the orifice of a sinus, or they may have their starting point in the constant irritation produced by the flow of foul and irritating pus. I have examined with the microscope a large number of aural polypi. They are composed of simple granulation tissue covered with epithelium, and there is no essential difference between the structure of a soft, florid, aural polypus and the fungous granulations that are seen about a sinus leading down to a diseased femur or a necrosed jaw. Its form is merely determined by the confined conditions in which it grows. The more rapidly the polypus increases, the more it is encouraged by the injudicious warmth and moisture of poultices and fomentations, the softer it will become. Its structure will then be almost myxomatous. Aural polypi which have grown slowly and lasted long will be fibrous in consistence, and covered on the surface by well defined flattened epithelium. Different names are given to varieties of aural polypi derived from their consistence and colour. Such are the "raspberry polypus," soft and friable, the "œdematous polypus," the "gelatinous polypus," and others. For purposes of practice, however, it is far better to look upon these growths as representing embryonic tissue in different stages of development.

In rare cases polypi are extremely vascular, large quantities of blood flowing from the ear when they are in any way interfered with; to this variety the name of "angiomatous polypus" is applied. True sarcomatous polypus is exceedingly rare. It is difficult, if not impossible, for the most experienced histologist and pathologist to certainly distinguish by the microscope between embryonic granulation tissue and rapidly growing sarcoma. The structure of both may be identical. Accordingly, when these growths were removed, and recurrence took place, it was frequently assumed that this recurrence was due to some inherent malignant qualities in the growth itself; the fact that recurrence of the growth was dependent upon the persistence of the local conditions that originated it was lost sight of. In a recent issue of the "Archives of Otology" I have related a case of this nature which is of very great importance. The polypus in this case was microscopically pronounced to be sarcoma by one of the best pathologists in this country; but the results of operation make me tolerably certain that it is not so, but that the growth was luxuriant granulation tissue dependent upon a fistulous sinus, from the mastoid to the bony canal, near the drum.[1]

In the treatment of aural polypus these growths must be looked upon as symptoms of a local disease, which needs much care and attention after removal of them. If a polypus be removed, and nothing further be done, the patient will undoubtedly obtain great temporary relief, but he will as undoubtedly again present himself for treatment suffering from another growth. Thus it is not infrequent for patients to tell us that they have had a polypus removed two, three, or even more times. Before, therefore, undertaking the treatment of one of these cases, it is well to impress upon the patient the great importance of a long continuance of after-treatment. Five or six weeks of attention after the operation are frequently needful, and intermittent inspection and treatment for several months after this; while the patient must, as long as he lives, studiously carry out those local and hygienic measures so important in perforative otorrhœa. True malignant disease attacking the temporal bone in the form of epithelioma or sarcoma is characterised by progressive and inveterate increase, severe lancinating pains shooting along the course of the branches of the fifth nerve, watery and bloody discharge, and rapid emaciation and cachexia from pain and exhaustion. We can hardly compare such a case with aural polypus. The diagnosis of polypus is always easy when the growth is large; a small deeply seated polypus may be readily overlooked. Such a growth will perpetuate otorrhœa indefinitely. Hence it is very important to carefully cleanse the ear by syringe and wool before inspecting it. Polypi have also been mistaken for exostoses. The latter class of growths are slow in progress and pale in colour, besides being definitely dense and osseous to the probe. In secondary syphilis condylomata have been known to occur in the auditory canal. This is rare, and we should be guided by the other signs of early syphilis, which would be probably strongly marked in such a case.

Before discussing the active treatment of aural polypi, it is necessary to say that these cases are not devoid of risk. The parts implicated have been long bathed in virulent septic fluids, and general pyæmic infection may follow the opening up of small venous trunks. Again, the operation may precipitate such serious cerebral lesions as meningitis or thrombosis of the lateral sinus. This is especially apt to occur when the case is neglected after operation, exposed to the bitter cold of an east wind, or allowed to become offensive and suppurate owing to want of cleanliness. For this reason one never undertakes these cases in out-patient practice without the apprehension of some mishap. Yet another caution. Persons suffering from polypus of the ear often delay operation until they or their relatives are alarmed by severe and dangerous symptoms. Thus a patient may apply for relief when he is already suffering from lateral sinus thrombosis, incipient meningitis, or even cerebral abscess. Here the polypus is but a small matter compared with the grave conditions alluded to. If we remove a growth from the ear without recognising such other serious conditions, we shall be unprepared for the probable fatal issue, for which the friends will blame us and the operation. Symptoms of urgency in cases of aural polypus are attacks of pain, vertigo, and sickness, and there is nothing more difficult to determine in practice whether such symptoms are due to mechanical pressure of the polypus and retention of discharge or are significant of some more serious condition.

It is always advisable, if possible, to well purify the ear before operating. This I usually carry out by syringing with warm carbolised or boracic lotions, and soaking the growth in warm alcoholic solutions of boracic acid. In addition to lessening the risk of septic infection these measures cause some shrinkage of the growth and diminu-

[1] Sarcoma is not frequently associated with necrosis and suppuration, but usually grows from a "healthy" bone. The excessive fungous granulation tissue originating in necrosis has often been mistaken for malignant disease. This is especially the case in the upper jaw.

tion of hæmorrhage. The best position for operating is the recumbent one, with the head high. The parts should be well illuminated by the electric light or the forehead mirror, with a strong lamp or good daylight.

As regards operative treatment, aural polypi may be advantageously considered under the following headings:—(1) The pedunculated polypus; (2) the flat, sessile polypus, and polypoid granulations. The pedunculated polypus may project beyond the meatus, or may be very small, not larger than a No. 1 shot. The larger the growth, the more easily it is detached. There is nothing more difficult than the removal of a small, deeply seated aural polypus. I prefer the snare for all pedunculated polypi of any size. Special features of this particular instrument are the fine wire and exceedingly slender barrel. (See Fig. 1.) By means of the special rack-and-pinion arrangement in the handle, the growth is securely held as the wire is tightened. This instrument is invaluable, I think, for small, deeply seated pedunculated growths. It is essential that the wire loop be well pushed down towards the stalk of the polypus, and then the latter readily comes away on traction. Smart hæmorrhage, checked by warm syringing, ensues. There are various patterns of forceps, including the time-honoured "lever-ring" forceps of Toynbee. I especially invite attention to this fine and slender modified ring forceps, which has the serrated teeth of an artery forceps in the ring, and a clamp catch in the handle. Any

FIG. 1.

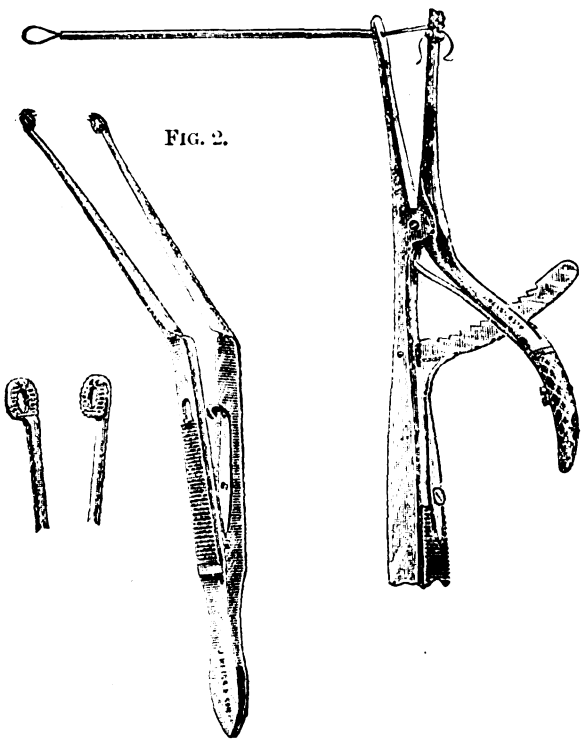

FIG. 2.

small polypus can be deliberately picked away with this instrument. The clamp catch prevents the possibility of slipping, and this forceps is one of the most useful I have ever employed for deeply seated growths. (See Fig. 2.) Some surgeons prefer to twist off pedundulated polypi with the forceps; others use the method of rotation, the growth being several times twisted on its own axis; the nutrient vessels of it are thus strangulated, and sloughing and extrusion ensue. This method is only applicable to polypi with defined and slender stalks. The treatment of sessile growths and polypoid granulations is more unsatisfactory. They are difficult to grasp. No snare will encircle them. They may be attacked after the following methods. First, they may be lacerated and broken up, portions of them torn away, and then some powerful caustic, preferably pure chromic acid, applied to them. They may be destroyed [illegible] cautiously employed, or extir- [illegible]ing knife. [illegible] is what [illegible]mirable results with a minimum of risk. The application of such materials as chromic acid, potassa fusa, or perchloride of iron may give rise to very acute pain, and in the young or nervous this proceeding is best done under anæsthetics. When growths originate from the walls of the canal external to the drum their site may be attacked with confidence and vigour. Many of them will be found to originate round the orifice of a sinus, leading backwards towards the mastoid. Some will be dependent on superficial caries or necrosis easily reached. I know of no better or more radical means of dealing with these growths than by the sharp curved curette, combined with the application of the galvano-cautery or chromic acid. The operation is tedious owing to the free oozing. Frequent hot syringing and cotton-wool pressure are requisite at intervals, and the operation should never be proceeded with when the parts are obscured by bleeding. It here becomes requisite for me to speak of the operation of curetting out the tympanum in the cases of intra-tympanic granulations or polypoid growths. This operation is growing in favour, but it should be undertaken, in my judgment, with exceeding care and discrimination. The surgeon has to remember that he is dealing with a cavity whose near surrounding anatomical relations are vital. And how can anyone be certain of the exact pathological condition he is about to attempt to relieve? Is the carious bone in the roof of the tympanic cavity or on its inner wall? Supposing that by the delicate use of a probe we ascertain its site, should we briskly use sharp instruments to remove it in the immediate vicinity of the meninges, the jugular vein, or the trunk of the facial nerve?[2] Do we not know that the bony partitions which separate them from the tympanum are often incomplete? How frequently do the mastoid cells participate in these cases, and should not surgical treatment be rather drawn to them than the tympanic cavity? These are some of the objections that come before my mind at this moment to these operations. Increased knowledge may bring increased confidence, but at present I would confine myself, so far as intra-tympanic operations for necrosis are concerned, to the removal of sequestra that are loose and easily to be extracted. Thus, we may cautiously remove the ossicles if loose and carious, and any loose fragment of bone which may show itself in the tympanum. In this way considerable portions of the petrous bone have separated and have been removed without mishap.

After removal of a polypus from the ear the patient must be clearly warned of the great liability to recurrence, and he should present himself at intervals for many months for careful inspection. For some weeks after the operation the site of the growth should be persistently treated with caustics so long as any evidence of living tissue remains in the stump. How and when this is to be done is a matter to decide for each individual case, but it is better to proceed cautiously, rather doing too little than too much, and to apply powerful remedies only to the stump or site of the growth under a good light. When aural polypi are treated in this way the results leave nothing to be desired, and the cases are among the most satisfactory in surgery. Want of care, and especially of patience, in the after treatment will certainly lead to disappointing results. The question of opening the mastoid cells will often arise in these cases, with a view to effect free drainage. If there are fistulous openings about the mastoid, it is well to enlarge these cautiously with a rose-headed drill, and with blunt scoops evacuate any "cheesy" débris. If there are definite signs of mastoid suppuration, especially intense pain and localised tenderness, this operation should not be delayed as a general rule.

I trust that sufficient has been said to show the lines of treatment to be adopted in these cases. I may, however, in conclusion, summarise my remarks by saying that aural polypi are usually the consequences of neglected otorrhœa, and should seldom occur were such cases properly treated. They are sources of great misery and discomfort, and sometimes of danger. They should usually be removed as soon as detected. The cases are never devoid of some risk. No one should undertake them unless he is confidently able not only to remove the growth, but also to carry out the after treatment so essential in these diseases, and to meet any untoward complications which may unhappily occur [illegible] the case.

CLINICAL OBSERVATIONS ON EXALGINE.

By JOHN GORDON, M.D.,

ASSISTANT TO PROFESSOR OF MATERIA MEDICA, UNIVERSITY OF ABERDEEN; PHYSICIAN TO THE ABERDEEN GENERAL DISPENSARY; JUNIOR SURGEON TO THE SICK CHILDREN'S HOSPITAL, ABERDEEN.

EXALGINE, which was first obtained from benzene by Brigonnet, and formed the subject of a communication to the French Academy of Sciences by Drs. Dujardin-Beaumetz and Bardet in 1889, is methyl acetanilide. Its formula is $C_9H_{11}NO$. It is one of a series of methyl derivatives from acetanilide (antifebrin). It is prepared by warming together monomethyl aniline and acetyl chloride. The reaction once set in motion takes place with rapidity. The methyl acetanilide is obtained from the mass by dissolving it in boiling water and crystallising out. Exalgine exists in acicular crystals, only soluble with difficulty in water, but readily soluble in dilute or concentrated alcohol. Its taste is slightly bitter, leaving a sensation of numbness on the tongue. The following is a useful formula to prescribe it:—Exalgine, forty-eight grains; compound tincture of cardamoms, one ounce and a half; syrup of orange, one ounce; water to six ounces. A tablespoonful for a dose. For exalgine it was claimed that it was akin in its pain-relieving properties to antipyrin and antifebrin, but that its analgesic action was secured by a much smaller dose and without the marked antipyretic and diaphoretic effects of these drugs.

The diaphoretic action of these substances, especially that of antifebrin, was complained of by some patients. It was also maintained that, although the local pain was abolished in a short time after the exhibition of exalgine, tactile sensation was not interfered with; that, in fact, no visible change took place in the outward condition of the patient. It had thus a distinct advantage over many other anodynes, in so far that the patient need not be hindered from his ordinary duties while under the influence of the drug. Its action, since it does not diminish general sensibility, is supposed to take place in those parts of the sensory nervous system which have for their function the perception and conduction of painful impressions. In some cases it has been recorded that disagreeable symptoms were noticed following doses of three grains, or after doses of six grains and upwards. In these cases there appeared evidence of cerebral disturbance, such as a feeling of intoxication, dizziness, buzzing in the ears, also of nausea, vomiting, and headache. In the numerous cases on which this contribution is based nausea, with an inclination to vomit a short time after the dose had been taken, was met with only twice. One of these patients was taking thirty-six grains in twenty-four hours; the other had twenty-four grains in a like period. None of the other unpleasant symptoms which have been noticed were complained of by those who took the drug. The class of patients to whom, for the most part, exalgine was given were those suffering from pain of the neuralgic type. The results obtained from this class of cases were distinctly satisfactory. All the patients to whom the drug was given were not cured; nor was the relief from the painful impression always permanent. But a large number showed a marked alleviation of pain in from half an hour to an hour or two hours after the exhibition of the drug, and frequently a permanent relief was obtained. In cases of nervous headache, especially in females, the action of exalgine in removing the pain was as distinct as it was speedy. The analgesic action was more quickly obtained if the patient assisted the drug by rest in bed. But this condition was by no means imperative. Sick headaches were also controlled by its use. In cases of toothache, sciatica, lumbago, intercostal neuralgia, locomotor ataxy, and otitis media, its exhibition was followed by good results. It was employed in doses that varied from one grain to ten grains, as many as thirty-six grains having been given in twenty-four hours. The results from a number of the cases showed that the smaller doses—such as half, one, or two grains—have not markedly analgesic effects, but that when the doses were increased to four grains a distinctly more potent influence was manifested. Other cases, in which the pain yielded slowly to doses of four grains, were speedily cured by eight grains. The dose which has been most frequently given was four grains, repeated every four hours till the analgesic action was evident. It is stated that the toxic dose of exalgine is three grains for every two pounds of body weight.

Professor Fraser of Edinburgh, in his valuable and interesting clinical lecture,[1] shows that he obtained marked analgesic action by doses of half a grain or a grain. But the larger doses of from four to six grains, as recommended by French observers, have given more satisfactory results to this writer; and it is interesting to notice in the recorded cases the relation between the dose and the time in which the pain was relieved. Types of the various cases, with the observations recorded, are herewith detailed. Examples from those suffering from facial neuralgia may first be given.

Facial neuralgia.—M. C——, aged fifty-eight, suffered from neuralgia of the upper division of the fifth nerve for a few days, severe in character.—Oct. 2nd, 1891: At 6 P.M. four grains of exalgine were administered. At 8 P.M. the patient stated that the pain was very much better, but still bad.—3rd, 10 A.M.: Pain very severe. Eight grains of exalgine given. 11 A.M: Pain gone.—Nov. 8th: Neuralgia of a like nature again complained of. 6 P.M: Eight grains of exalgine ordered. 8 P.M: Pain wholly removed. Had no return of neuralgia till Jan. 4th, 1892. 6 P.M: Eight grains of exalgine given. 8 P.M.: Quite free from pain; the pain, she states, began to subside about half an hour after the dose was taken.

N. A——, aged fifty; neuralgia of first and second division of fifth nerve. Tenderness on pressure on nasal branch; had continued for six days.—Jan. 15th, 1892, 6 P.M.: Four grains of exalgine given; patient felt too ill to leave her bed that day. Half an hour after taking the drug she began to perspire gently. Slept lightly. 10 P.M.: Pain and tenderness considerably relieved. Four grains again given. Perspired freely about half an hour after taking the powder; slept most of the night.—16th: Slight headache in the morning; tenderness gone. 10 A.M.: Another four grains of exalgine were administered. 1 P.M.: Pain quite removed; able to begin duty at 3 P.M.

Toothache.—The following case of toothache, which was accompanied by tenderness in the inferior dental nerve, is interesting as showing the influence of exalgine in controlling cases of pain where there is inflammatory action:—J. A. F——, aged thirty. Toothache and frontal headache.—Jan. 3rd, 1892: At 8 P.M. he took four grains of exalgine. 9 P.M.: Pain gone.—4th: Pain returned in the afternoon. 6 P.M.: Four grains of exalgine given. 7 P.M.: Pain relieved.—5th: Pain recurred, similar in character. 6 P.M.: Four grains of exalgine given. 8 P.M.: Pain had gradually abated till that time, when it quite ceased.—6th: Pain had again returned. 7 P.M.: Four grains of exalgine given. 8 P.M.: Pain ceased.—7th: Pain again present. 6 P.M.: Four grains of exalgine given. 7 P.M.: Pain once again removed. In this case the evidence of the analgesic action of the drug was constant and marked. As a rule, this patient was free from the pain till the afternoon of the day following the administration of the exalgine.

Headaches.—J. M——, aged thirty four, complained of frontal headache. Tendency to vomit. Temperature 98·6°. Bowels regular. Headaches have for years been frequent.—Oct. 18th, 1891, 1 P.M.: Ordered four grains of exalgine. 2 P.M.: Headache considerably relieved; nausea gone. 3 P.M.: Four grains of exalgine given. 3 30 P.M.: Pain and nausea quite better.—26th: Headache of a similar character to that noted on Oct. 18th. 10 A.M.: Eight grains of exalgine ordered. 10.30 A.M.: Pain very much better. 10.30 A.M.: Four grains of exalgine ordered. 11 A.M.: Pain quite relieved; nausea also.—Nov. 5th: Headache, supposed to have been induced by excitement. 8 P.M.: Eight grains of exalgine taken. 8.30 P.M.: Headache quite better.—Nov. 7th: Headache. 7 P.M: Eight grains of exalgine given. 7.30 P.M.: Pain quite relieved. This patient stated that the larger doses (eight grains) were far more satisfactory in easing the pain, as the action began within ten minutes after the dose; that no disturbance of any kind took place while the drug was taken; and that since November the headaches have been far less frequent than they were for some time past.

R. N——, aged thirty-five, recently suffered from biliary calculi. Slightly jaundiced. Severe frontal headache of four days' duration.—Jan. 8th, 10 A.M.: Two grains of exalgine were prescribed. 2 P.M.: Headache

slightly better. 6 P.M.: Another two grains of the drug were taken. 7 P.M: Headache relieved.—10th: Complains of headache. 2 P.M.: Two grains of exalgine ordered. 6 P.M: Pain considerably relieved. Two grains of exalgine given. 8 P.M. Headache quite better.—14th: Headache. 9 A.M.: Two grains of the drug given. 3 P.M.: Headache relieved.—16th: Headache. 6 P.M.: Four grains of exalgine ordered. 7 P.M.: Headache quite gone.—18th: Complains of severe pain in the region of the liver, stomach, and in the umbilical region, with slight tenderness on pressure; nausea; no vomiting. Temperature 98·6°. 10.30 A.M.: Four grains of exalgine taken. 12 A.M.: No relief from abdominal pain. 12 A.M.: Four grains of exalgine given. No ease to the pain followed the second dose. Two grains of opium, along with mustard leaves and poultices, were ordered, and the condition improved, till at 8 o'clock P.M. the pain was quite gone.—20th: Severe frontal headache, with orbital pain. 5 P.M: Four grains of exalgine given. 6 P.M.: Pain considerably relieved; four grains of exalgine taken. 7 P.M.: Pain entirely gone.—25th: Headache. 4 P.M: Four grains of exalgine administered. 5.30 P.M.: Headache quite relieved.
